Water C[illegible]ing on Motor Bicycle Engines.

THE MOTOR CYCLE

1D

No. 354. Vol. 8. MONDAY, JANUARY 3rd, 1910. Price 1d.
REGISTERED AS A NEWSPAPER FOR TRANSMISSION IN THE UNITED KINGDOM. Published Weekly.

Go to WAUCHOPE'S

The Motor Man

9, SHOE LANE, FLEET ST., LONDON.

He will satisfy you and please you. He deals successfully for fair exchanges—he is very unique. 1910 models from stock, fair price for your mount. Wauchope's won't worry you.

"MILLFORD" SIDECARS.

"With my 'Triumph' Motor Cycle and 'Millford' Sidecar I can take a passenger of 11 stone to Brighton and back on less than five quarts of petrol (it takes four for the cycle alone). Do you know of any other combination that will take two persons 100 miles for fifteen pence?"

So writes Mr. W. M. Sinclair, of Herne Hill, on Dec. 13th.

PRICES TO SUIT ALL POCKETS.

List free from all Motor Cycle Depots or the makers:

Three Sidecar Improvements.

These excited universal approval at the Stanley, viz.

1. Improved spring wheel, on motor car lines, and giving a smooth free action without jar.
2. Improved springing under foot of chair, totally eliminating vibration from the passenger's seat.
3. Instant attachment of back support to seat bolt or motor cycle. Save time and language. Above are all provisionally patented.

THE COWEY SPEED INDICATOR

FOR MOTOR CYCLES, WITH OR WITHOUT SPRING FORKS.

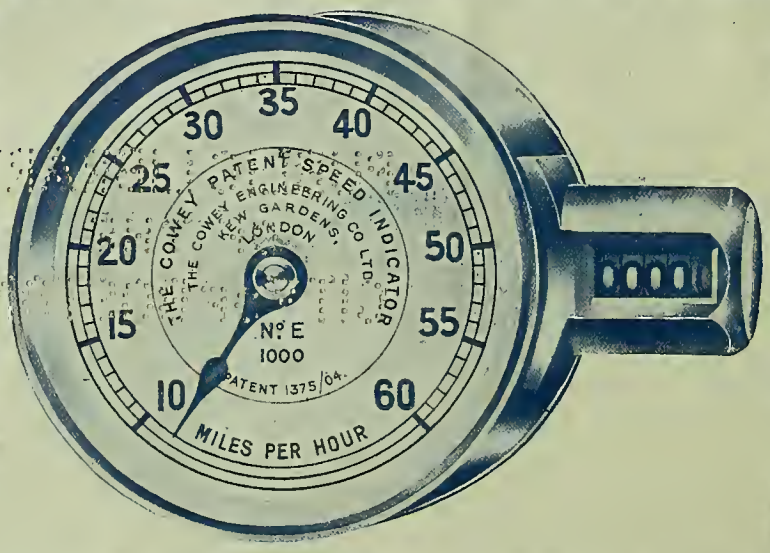
BRITISH MADE AND GUARANTEED AGAINST REPAIR CHARGES FOR 12 MONTHS.

Note the clear, open dial (actual size) which is attached to the handle-bar, and can be read at a glance.

With so many speed limits in force a reliable indicator is a necessity.

The COWEY is gear driven throughout, and is therefore reliable always.

The hand is perfectly steady at all speeds, a feature which is absolutely impossible in any other indicator.



CAN BE FITTED TO ANY TYPE OF SPRING FORK AND TO THE RIGHT OR LEFT HAND SIDE OF WHEEL AS DESIRED.

PRICE COMPLETE

£4 4s.

Registering to 60 Miles Per Hour WITH MILEAGE RECORDER, as illustrated.

Call or write for a copy of our Cycle Indicator Booklet, which will interest you.

NOT CENTRIFUGAL—NOT MAGNETIC—BUT POSITIVE.

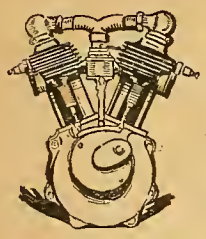
Quarterly Trials Regulations.

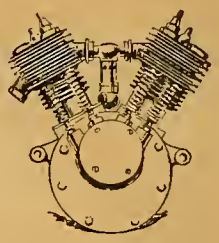
ONE of the clauses in the A.C.U. Quarterly Trials regulations will have probably caused as much wonderment to many of our readers as it has to ourselves, and its wisdom is certainly open to much question. We refer to the regulation which states: "A participant may not stop under any circumstances except at the bottom of Dashwood Hill and Rectory Hill, Amersham." As is well known, these two ascents are the ones on which competitors are observed and marks awarded for the hill-climbing capabilities of their machines. Consequently it is the more surprising that they are permitted to halt at the foot of these test hills *and cool the engines*. The object of stopping the riders is to enable the officials to send them up the hill singly and at fairly long intervals, so that, should traffic be prevalent or should a competitor find he was obliged to overtake and pass another on the gradient, he cannot complain that he was hindered or otherwise hampered in his ascent. This is all very well, but the same effect could be obtained in various other ways, such as by stopping the participants two miles from the foot of the hill, restarting them at intervals with instructions to proceed at legal limit speed, and forbidding a competitor to overtake the rider in front under penalty of disqualification. But to stop competitors in a 1910 motor cycle trial at the foot of two such comparatively easy gradients as Dashwood and Amersham, and then despatch them with cool engines, and call it a test of hill-climbing, is surely a mild form of slight to the wonderful hill-climbing abilities of present day motor cycles. If in touring, motor cyclists were content to dismount and allow their engines to cool before climbing hills of the calibre of Dashwood and Amersham one would have less cause for criticism, but the hills are little above the ordinary, and any machine which cannot surmount them with a *hot engine*—that is, after a non-stop run of several miles—is hardly deserving of the designation "present day motor bicycle." After all, motor cyclists particularly want to know if a machine is a good hill-climber when the engine is hot, as it is not every engine that will keep cool and continue to pull on a long gradient.

If the quarterly trials are to serve the useful purpose for which they were started, they must weed out the weaklings. At present the full distance of the day's run is but 125 miles, and how many genuine tourists are there who are satisfied with such a run, which represents six hours' riding at legal limit speed? And how many prospective buyers would order a motor bicycle on the strength of a single performance in one of these trials? Some of the competitors have to travel over double the distance to compete in the trial. No, the conditions generally are much too easy at this advanced stage of the pastime, and unless the trial is made more difficult by compelling competitors to commence the two climbs with hot engines we fail to see how manufacturers can regard a first-class certificate as much of a feather in their caps. We are entirely in accord with the new method of awarding a maximum of 200 marks, and are convinced that the classification under the different headings will be productive of much good.



TUNING UP.

Particularly applied to V type Engines.



IT is generally supposed that phenomenal performances obtained on twin-cylinder machines are due to illicit treatment, if I may term it such—for example, specially-constructed engines, special fuels, the use of picric acid, etc. This may have been the case, but it is undoubtedly possible to obtain a very much higher efficiency from a twin cylinder than is usually the case with the majority of such engines as normally fitted to motor cycles.

I propose to point out how this high efficiency can be obtained, and results achieved almost on a parallel with those obtained in the important hill climbs. A great many of the following remarks are applicable to single-cylinder engines, and the tuning up of petrol engines generally, but they apply more particularly to twin-cylinder engines.

"Tuning up" in the eyes of many consists merely in the grinding in of the exhaust valves, trimming up of the contacts and cleaning the carburetter. True these are the most important items in tuning up, but they can be done in different ways, some of which are right, but many are wrong.

Dealing first with the mechanical parts of the machine, it is necessary to see that the road wheels revolve perfectly free, that they "track," and that the brakes do not rub. If the machine is fitted with a band brake or a hub brake, it must be adjusted until the wheel will revolve freely. These simple parts are frequently overlooked.

Removing Carbon Deposits.

The cylinder or cylinders should then be taken off, the piston head scraped of all deposit, and polished as far as possible, as the deposit will not adhere so readily to a polished surface as to a rough one. The carbon deposit should be removed from the cylinder heads at the same time. For this purpose a screwdriver is probably as useful as anything. Some chemicals will remove it, but I have not tried them. If the deposit has set hard it will come away easily if it is first soaked with oil. For the piston head I find a knife is as good as anything. The deposit should be removed not only from the combustion chamber, but also from the valve chamber, and the whole left as clean as when new. Now the cylinder is off, the piston rings should be examined. If they are not bright all round, or nearly so, they should be removed and new ones inserted. There should not be much shake vertically of each ring in its groove, and it should be sufficiently elastic to exert a pressure on the cylinder wall. It should be noted that the ends of the ring, when it is compressed to fit the cylinder, should have about $\frac{1}{32}$ of an inch gap, the amount varies with the size of the piston, but if there is not some clearance the ring will bind when engine gets hot. The rings should then be spaced out so that their cuts are as far apart as possible.

Whilst the cylinder is removed both valves should be ground in, this work being much easier with the cylinder off the machine than on. In grinding in a valve it is advisable to use an excess of oil or paraffin rather than an excess of emery, and the pressure should be but moderate. Nothing is gained by excess of pressure or any excess of emery. The result generally is to score the face of the valve. Personally, I use a carpenter's brace and screwdriver bit. Underneath the head of the exhaust valve I place a spring, which just lifts the valve clear of its seat when the pressure is released, but allows it to be pressed down on to the seat. After spinning around the valve, or oscillating it, the pressure should be removed, allowing the valve to come off its seat. The valve should then be turned through a small angle and the grinding resumed. This allows the emery and oil to continue spreading over the faces, as of course under pressure they are forced out.

The Much Neglected Inlet Valve.

The grinding should be continued until the faces show clean all round, and this applies to the much-neglected inlet valve as well as the exhaust valve. The inlet valve rarely requires grinding, but is generally neglected, and on examination it is often found to be in a state that would account for considerable loss of power.

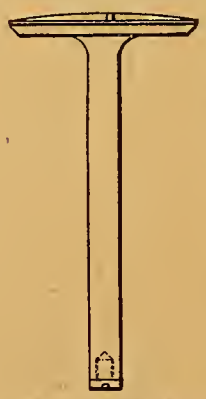


Fig. 1.—A simple method of lengthening a valve stem.

Before replacing the valves, the stems at the points where they pass through their guides should be rubbed with block blacklead so as to lubricate this part. Before the cylinder is replaced the crank chamber should be washed out with paraffin and refilled with oil to the right extent, and the cylinder, the piston rings, and cylinder walls should be lubricated.

The cylinders can now be replaced, and the clearance between the valve stems and tappets should be noted. The space should be as little as possible. If there be no clearance, the valve, when heated, will expand, and be held off its seat slightly at times when it should be seated, and thus the cylinder will lose compression. If there is too little clearance, the remedy is naturally to file a little from the valve stem. If there is too great clearance, either a new valve can be used, or a hole can be drilled and tapped in the end of the valve stem and a small screw inserted in the end, as shown in fig. 1. This screw can either be brazed or not, though personally I have found screwing in quite satisfactory. The head of this screw should then be filed down as required.

Tuning Up.—

With automatic inlet valves it is essential to see that the springs of the two valves are at the same tension. The method of doing this is shown in fig. 2. By holding the valve seats in the fingers and bringing the stems together, the two valves will be forced off their seats, that with the weaker spring being forced further open and opening sooner than that with the stronger spring. In the drawing the valve on the right is shown with the weaker spring to demonstrate this. If the engine is required to develop high power at low speeds the valve spring should be relatively weak, but a weak valve spring will not allow the engine to run at its maximum number of revolutions. If a high speed is expected from the engine, then strong valve springs should be used, and only a small opening.

The exhaust valve springs should be sufficiently strong to close the valve quickly, and should exert sufficient tension when the valve is shut to prevent the valve being sucked open when the engine is throttled down very much. Some springs are just sufficiently strong to seat the valves, but as they are compressed a few thousand times a minute for some months they naturally shrink slightly, and only hold the valve gently on its seat, and the valve is liable to be sucked open. Exhaust valve springs are cheap, and it is very important that new ones should be fitted when the engine is being tuned up at the beginning of each season, or before an important event.

In addition to the above the carburetter and silencers should be removed, which generally is an essential in order to take down the cylinders. The carburetter should be thoroughly cleaned, and any gauzes used should be cleared. If the carburetter is of the Longuemare type, it should be examined to ascertain the petrol level. The carburetter should be placed in position on the machine at the level at which it is normally fixed. The jet should be unscrewed, and the petrol turned on. The petrol will be seen to rise in the jet orifice, and will stop as soon as cut off by the float. Very often this point of cut-off is below the flared mouth of the tube. The petrol level should always be just on the flared or conical portion, otherwise capillary attraction will not take place, and difficult starting will be the result. To raise the level, a washer can be placed upon the float. If no advantage is derived from this, the washer can, of course, be easily removed. I state this because many carburetters, under vibration, have a higher level when running than when standing.

In the case of single jet carburetters it is advisable to obtain a dummy jet to check the level of the petrol. This dummy jet is the same height as the ordinary one, but larger in diameter, and bored out at the top to the full width of the tube.

An Important Point.

Now we come to the important subject of the size of jet in relation to the air passage past it, and this is one of the most important considerations, and is generally neglected by the ordinary user.

It is generally understood that the petrol is sucked from the jet by the air passing it. Normally, the quicker the air passes, the more petrol is taken up. To obtain more petrol, one can either make the jet bigger or the air passage smaller. By making it small, we increase the velocity of the air passing the jet, and increase the "suction," causing more petrol to be drawn out. It is advisable to use as large a choke tube or air passage as possible, and adapt the jet to it. The majority of Longuemare carburetters on the market are limited in the size of their choke tube, but in some cases the recess, into which the choke tube fits, can be bored out to take a larger one, and a larger jet can be correspondingly fitted. In any case, it is important that the air passage should be as large as possible compatible with ease of starting. I therefore suggest the fitting of the largest choke tube supplied with the carburetter, and, if the machine will not start easily or run slowly without flooding, fit a larger jet. If the largest jet supplied will not give the desired result, an extra cut can be made in the jet with the tip of a knife blade, if the blade is sufficiently pointed. The rider should then run his machine at the highest speed possible, opening up his air, and if at some speed short of the maximum, it will take all the extra air supplied with the throttle fully open, the extra air inlet should be enlarged, or an additional air inlet between the throttle and the carburetter be fitted. The possibility of supplying sufficient air at high speeds is very important in obtaining maximum efficiency, and to prevent what is called "overheating."

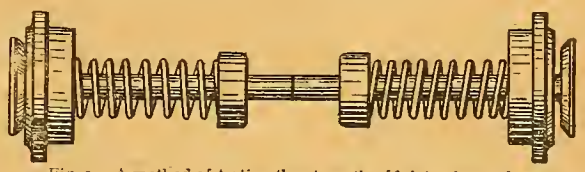

Fig. 2.—A method of testing the strength of inlet valve springs.

The silencer before being replaced should be taken down and cleared. This has to be done by a brush, as there is no solution known that will remove soot. Scouring the silencer will assist in preventing the deposit, but will not prevent it altogether.

Testing the Ignition.

Assuming the machine to be now assembled, it is necessary to test the ignition and tune it up. If the contact-breaker is of the wipe type, it should be cleared of all oil and lubricant. As a rule, the current has to find its way from the metal segment or segments of the contact-breaker to the "earth" through some moving part. If a wire can be fitted to conduct the current, a great advantage will be noticed at high speeds. If the contact-breaker is of the make and break type, as it should be to obtain the best results, a wire led from one contact blade screw to the crank chamber will effect this. I advocate a plain make and break contact-breaker, because the points are renewable, and because a non-trembler coil can be used. As twin-cylinder engines and most motor cycle engines are required to run over 2,000 revolutions per minute, it is essential to eliminate anything that causes any delay or uncertainty in firing. Most coil tremblers do delay or are uncertain at high speeds. Personally, I use a non-trembler coil and plain make and break, and have naturally found that the engine will run faster with this and fire better at high speeds than with a trembler coil. The contacts should be filed flat, and should be removed to do this, to see that the rivets are quite tight. A rivet that is slightly slack in a spring or blade will cause erratic firing, which is extremely difficult to locate.

Now comes the most important part—that of synchronising. For this purpose I use the implement

Tuning Up.—

shown in fig. 3, which I call a tuning fork. It consists of a wooden handle with a metal fork let into it. The sides of this fork are of unequal length for convenience in handling. An ordinary screwdriver will effect the purpose, but the tuning fork shown is easier to use.

The engine should be run slowly on the stand and the tuning fork held with one prong on the insulated terminal of the sparking plug and the other on the cylinder. This short circuits that particular cylinder, and the current travels from the insulated terminal of the sparking plug, along the tuning fork, and to earth *viâ* the cylinder. Care should be taken to hold the fork firmly against the sparking plug and the cylinder, as any joggling may cause the short circuited plug to cut in temporarily.

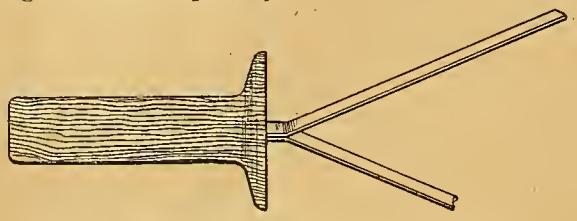

Fig. 3.—A tuning fork for testing the synchronisation of the firing.

The engine now runs on one cylinder, and its speed can be roughly estimated by the beats of the exhaust. When the engine has had time to settle down to a steady speed, and this speed is noted, the tuning fork should be moved quickly over to the other cylinder so as to cut out the other plug. The second cylinder now runs alone, and its speed can be noted. In all probability it will be found that one cylinder will not run at all at low speeds, or, if it does, it will run slower than its fellow. The platinum contacts on this cylinder must, therefore, be adjusted to operate earlier or later, as the case may be. To speed up any cylinder that runs slowly the contacts should be slacked off if a non-trembler coil is used, and adjusted closer together with a trembler coil.

Perhaps one comes to the end of one's adjustment without effecting the desired result, and, of course, the reverse operation should be performed on the contact for the other cylinder. By carefully adjusting these contacts the cylinders will be found to fire quite evenly. They should be tested at varying speeds, and, if possible, on the road. The tuning fork enables this to be done quite easily, as one can bend down and cut out either plug with the engine under load, which gives a better result than a standing test. There are also special sparking plug switches for effecting this.

Immediate Perfection Must Not be Expected.

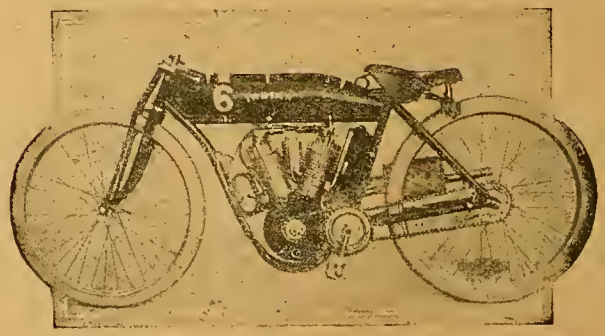
I have purposely mentioned the synchronising last, and it should be carried out after everything else has been done, and the cylinders should be tested again for even firing after running about fifty miles. As the valves have been ground in, the engine will not, as a rule, give its normal compression till it has run some little distance, and as the compression may be better in one cylinder than the other, it will affect the synchronisation. By keeping the synchronisation till last it compensates for any differences between the two cylinders.

The above remarks apply to machines fitted with accumulator ignition. With magneto ignition the necessity for this electrical adjustment does not arise, as the firing of the two cylinders is set correctly in the magneto, and seldom gets out of order, say, in less than twelve months' continual use. Even then the only renewals required are new contacts and perhaps new cams. It is necessary, however, for the magneto to receive attention, and this will be described in connection with a Bosch D.A.V. machine.

Adjusting and Timing the Magneto.

The contact breaker should be removed by removing the central screw which holds it to the armature spindle. When removed the contacts can be thoroughly examined and if necessary trimmed. The contact breaker can then be replaced, care being taken to see that the spring contact or brush at the back of the base plate is in place, and that the central screw is screwed up tight. The bearings should be oiled and the high tension brushes removed, examined, and wiped. It will generally be found that even this small amount of attention is not necessary, as these magnetos perform continuous service with hardly any attention at all. It is, however, important to see that the timing of the magneto is correct, and particulars of this can be obtained from the handbooks issued by the makers of the particular magneto fitted. A little experimental adjusting of the magneto timing one way or the other will be beneficial. For this purpose a reliable speed indicator is of considerable service in order to ascertain the effect of slight changes in the timing.

It is hardly within the scope for an article with this title to refer to gear, but I may be pardoned for doing so. It is generally the case that a machine is geared too high for hill-climbing, usually because the engine will not run above, say, 1,800 or 2,000 revolutions per minute. If tuned up as I suggest, and fitted with a good make and break contact with plenty of advance or a magneto, the engine can be run up to and well over 2,000 revolutions per minute, enabling a lower



The first 7 h.p. twin-cylinder Indian to arrive in this country. We referred to it last week as having been seen at Brooklands. As will be observed, it is a larger replica of the now famous 5 h.p. model.

gear to be fitted and better work to be got out of the engine all round. On the steep parts of a hill the engine speed does not fall below 1,800, whilst on the easier portions it will be running at its maximum speed, enabling practically full power to be got out of the machine on all gradients.

The machines used in many of the important hill-climbs may, in some cases, have been "faked" in various ways, but it is astonishing what a lot can be done by a general tuning up on the lines suggested.

ERIC W. WALFORD.

The Trusty Triumph

The "Jarrott Cup," won by Mr. F. G. Smith for the M.C.C. 48 hours' ride from London to Land's End and back on a Triumph.

However powerful, however speedy, however comfortable a motor may be, but lacking reliability, is of little pleasure to the rider.

Weaknesses are for ever being revealed, faults develop in the most unlikely places, and at most unfortunate times, so that no reliance can be placed on the motor for any ride of average length.

The Best is Cheapest—for whatever little extra you pay in the first instance for reliability is quickly repaid by the smallness of your repairs bill.

The Triumph Motor has this trinity of virtues—Speed, Power, and Comfort—and under the severest tests in our own and private owners' hands has revealed its absolute reliability.

It has proved over and over again its quality, its worth, and the reason why it is always "on top."

Silver Cup presented to Mr. Ivan B. Hart Davies by the Triumph Cycle Co., Ltd., in recognition of his magnificent End-to-end Record on a Triumph.

May we send you our preliminary list, pending the publication of complete catalogue, post free.

C.D.C.

In answering this advertisement it is desirable to mention "The Motor Cycle."

Water Cooling on Motor Bicycle Engines.

ON reading the above title many motor cyclists will scout the idea that water cooling is necessary or even desirable on motor bicycles. But on further consideration, when so many complaints are heard of valve troubles, overheating troubles, the rapidity with which working parts wear, and last, but not least, the frequency with which it becomes necessary to clean the cylinder heads and pistons of some engines, any means which will either totally prevent or even mitigate all or any of the above troubles calls for careful thought.

In many cases the dismounting of a cylinder is no small matter, and, even if it is a comparatively simple job, it is an extremely dirty one, and, moreover, a task which should not be necessary oftener than once a year.

Early Experiments.

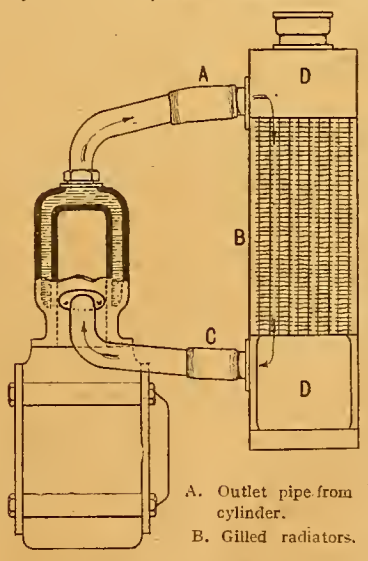
Unfortunately, not very much has been done, in public at any rate, regarding experiments in this direction. Rather over six years ago a French importation known as the Iris was sold at a small shop in Brixton, made in two models, single and twin, to both of which, water-cooled cylinders were fitted. The water compartment was carried separately from the fuel and oil tanks, and had tubes running through it, which acted as a sort of radiator. But the firm exploiting the machine closed its doors before much more was heard of it than the usual technical description in *The Motor Cycle*. Later a well-known firm of accessory factors imported also from France an experimental chain-driven, water-cooled motor bicycle known as the Bruneau, which I rode for some time. It was rather better made than the Iris, was a marvellous hill-climber for its size, more efficient by far than the average motor bicycle, and totally devoid of knock.

Next there came under my notice a machine built to the order of a private owner fitted with an engine possessing a water cooled head—none other than the famous White and Poppe, a few of which were turned out so constructed about five years ago for light tricars. The amateur in question was enthusiastic to a degree about his mount, and declared that no air-cooled engine of equal size could live with it. He carried out the circulation system very carefully, and never experienced trouble either from the water boiling or from leaky connections.

Green's Patent Water Jacket.

Following on this my attention was called to Green's water jacket and radiator combined—a most ingenious device invented by Mr. Green, of Bexhill. The device consisted of a copper water compartment, provided with pipes running through it to ensure good cooling, which fitted over a finless cylinder, and to the bottom of which a rubber joint was supplied to make the whole watertight. It was first fitted to a few Rex engines, and was entered for one of the A.C.U. hill-climbs at Birdlip, but did not compete. It was tried by a well-known firm of motor cycle manufacturers, who did not adopt it. However, I still hope to hear more of it, as an adaptation of the idea is now embodied in the Aster aeronautical engine now made under Mr. Green's patents.

Lastly, we have the famous Scott motor bicycle, which is at present the only machine actually on the market which is water cooled. In the days of the popularity of the motor tricycle a water-cooled head was used with remarkable success by the makers of the De Dion tricycle, also the makers of the Ariel tricycle. Mr. C. A. Smith, treasurer of the Auto Cycle Union, still uses two of these splendid old stagers. One has a water-cooled head, and the other is only air cooled. Of the two Mr. Smith reports that the water-cooled engine is the more powerful and the more reliable of the two. From these accounts it may be fairly accurately deduced that, size for size, the water-cooled engine is decidedly more powerful, but it must be borne in mind that greater weight is unavoidable. I also seem to hear someone say, "Greater complication also." But surely a complication which gives no trouble neither deserves the name nor even can be said to exist as such. All improvements may be called complications until they are tried, but when they are tried and their presence does not make itself known the opprobrious term falls into oblivion. All depends upon the way in which the cooling arrangements are carried out, and if the waterways are of sufficient size, the cooling surface of the radiator is ample, and the joints are properly made, there should be no trouble.



A. Outlet pipe from cylinder.
B. Gilled radiators.
C. Inlet pipe to cylinder.
D.D. Water tanks.

Water Cooling on Motor Bicycle Engines.—

Water-cooling is, of course, only suitable for heavy and mediumly heavy touring machines of 3½ h.p. and over. The lightweight will always remain air-cooled; but I am confident that sooner or later many machines will be born which will be water-cooled, and that successfully, and without adding greatly to the weight. Should this ever come to pass—and it is quite possible—the slide valve engine will be *un fait accompli*, and a new era will dawn upon the motor cycling world. The one and only cooling system suitable for motor cycles is the thermo-syphon, which novice readers may care to have explained. The principle is this: It is well known that hot water is lighter than cold water. Consequently, as the water surrounding the cylinder is heated by the explosions, and has always the weight of the cold water in tank and radiator bearing upon it, it rises and passes through the delivery pipe A. It then has access to the radiator B, consisting of numerous gilled tubes which, offering a large surface area to the air, rapidly cool the water. The moment the hot water begins to rise through A it is replaced by the cooler water in tank and radiators which enters the cylinder jacket through the return pipe C. In a correctly arranged system some portion of the tank and radiators is always above the highest point of the water-jacket, and the pipe A where it enters the tank should always be covered with water. For that reason it is made to enter the tank at a prearranged distance from the top. The sketch on previous page shows a system that has been used on several different tricars, notably the Rex Litette and Singer. In this system the outlet pipe from cylinder is made to enter at bottom of top tank. Thermo-syphon cooling is simple and reliable, and the only two necessary conditions are large pipes and an ample radiator. Naturally, to render success a certainty the best workmanship is necessary. In these days of two-speed gears and the ever-growing popularity of passenger attachments, it seems that greater attention should be paid to water-cooling. The Scott has been the first machine to lead the way in a serious manner. Who will be the next to follow?

AILETTE.

THE TRANSMISSION QUESTION.

THERE are few things on a modern motor bicycle which can be so readily criticised or about which there is such diversity of opinion as the transmission of power from the engine to the back wheel. It appears that the choice between what may be termed flexible and rigid transmissions is still, and probably will remain for a considerable time, a matter of personal sentiment. When one hears experienced riders say that they would on no account ride a machine on which the power of the motor is directly conveyed by gear or chain to the rear wheel it can only be supposed that the prejudice is shared by less experienced riders.

Ignoring chain and gear transmissions unprovided with some form of clutch or slipping medium between engine and road wheel, we come next to the most usual form of transmission on motor cycles, which is, of course, the belt.

Smoothness of Drive.

Now, considering the fact that no belt is capable of extending and contracting to the amount necessary to give a flexible drive, it is obvious that the so-called flexibility or smoothness of transmission is due to a momentary slip of the belt over the smaller pulley. This slip occurs at each explosion or sudden impulse of the engine, and is very hard on the belt, tending to shorten its life and stretch it unduly. We have therefore to strengthen the belt to withstand great tensile forces, yet at the same time its fibres when in tension must be capable of easy curvature to enable it to follow the circumference of the pulley without offering much resistance or without taking up too much power in bending. What is required is a combination of the flexibility of a chain with the adhesive qualities of a leather or rubber belt.

I only know of one belt which combines these qualities in an efficient manner, and that is the Whittle link grip belt. Now I am not in the least interested in the firm who makes the belt except that I have purchased a belt, and since the date of that transaction I have had no more trouble with transmission.

Previously I tried all kinds of belts—plain leather, leather strips built up in various ways, and, of course, our old friend the rubber and canvas belt. The great popularity of the last-named type seems to be due to two causes:

(1) The resemblance of the majority of motor cyclists to a flock of sheep.

(2) The ignorance on their part of anything better.

I used to have no end of trouble with slip, breakages, fasteners, and the like, not to mention a large bill for belts at the end of the year. At one time I never ventured on a long journey without a spare; now I have no need for such a thing.

I was repeatedly warned by other motor cyclists not to have a Whittle. They said it was heavy and expensive, would wear out the pulleys, would need constantly cleaning, scraping and dressing, was messy, and so on. In face of this opposition I decided to try one, and have used it on a Triumph machine which has been ridden in the worst storms and over the vilest roads it has ever been my lot to see.

One night after returning from an unusually bad ride even for these northern latitudes (N.E. of Scotland) a man came into my garage to see the machine that had braved such elements. What was the make? Triumph. What were the tyres that did not skid even on those roads? S.E. studded. And what was the belt? Whittle. That belt had been running for 4,000 miles, and looked like doing a similar distance again. It gets cleaned and a little dressing smeared into it about every six weeks. But wait; perhaps the pulleys are worn to the bone. No, they seem untouched. Perhaps the power taken up in turning such a belt is appreciable. No, I have never found that, and forty-seven miles per hour by stop watch in touring trim does not confirm the idea.

Its opponents must think of some other disadvantage before they shake my faith in it.

MOTOR CYCLE RECORDS, 1909.

Specially compiled for "The Motor Cycle," by J. Sinclair.

For years past it has been our custom to publish a list of motor cycle records at the close of the old year, and this, the first issue of the New Year, contains a list of British and Continental Records existing on December 31st last. It is the most complete list in existence. In a subsequent issue a list of American records as officially recognised by the Federation of American Motor Cyclists will appear. It is obviously impossible to publish in this issue a complete list as standing at the end of 1909, but the authentic list from the F.A.M. is now on its way to us and may arrive in time to be published next week.

MOTOR cycle record-breakers at home have been fairly busy during the past year, as, with the exception of the hour, all the middle and long-distance figures have been altered, H. V. Colver and H. A. Collier being responsible for the principal changes. The decision of the Auto Cycle Union to recognise class records has resulted in many new names figuring in the record sheets, and there is not the slightest doubt that the innovation has proved a success, as, apart from affording owners of various powered machines a chance of distinguishing themselves against the watch, the respective speed merits of all classes of motor cycles on the market can be officially tested. Class C, for engines not exceeding 500 c.c. capacity, has found several new aspirants to record fame, G. Lee Evans having appeared very prominently, but late in 1909 O. C. Godfrey annexed the hour and fifty miles records in this particular class. On the Continent the cracks have been particularly quiet, the only rider to be successful being Jean Olieslagers, who did some extraordinary times at Antwerp, covering one lap on a small wooden track at a rate of 72¼ m.p.h.

In America all records have been swept by the board at the new Springfield Stadium. F. Huyck was successful in establishing new figures up to the hour, while Charles Spencer and Charles Gustafson put up new figures up to twenty-four hours.

1910 promises remarkably well, as already several well-known record-breakers have announced their intentions of setting up some sensational times and distances, particularly in view of the fact that the Americans are now well in the field as regards record-breaking. Thanks to the large track at Brooklands, and the exceptional facilities granted by the popular Major Lindsay Lloyd, British motor cyclists have now an excellent opportunity of distinguishing themselves against the watch. During the past year some very

A USEFUL MOTOR TRICYCLE.

IN *The Motor Cycle* of December 20th, our contributor "Ixion" made the following remarks in his comments: "Personally I don't favour the two front wheel steering type of motor tricycle; minus a good heavy weight over the front axle it is about as miserable to sit as anything I know." "Ixion" has evidently not tried the 2¼ h.p. two-speed F.N., on which we enjoyed a run the other day over the vilest and heaviest of London roads. Owing to its short wheelbase, the low position of the engine, and the careful distribution of the weight, the machine is particularly well balanced, and though it would appear to the casual observer to be likely to be uncomfortable on very rough roads, we can assure our readers that this is not the case. No better testing ground than Portland Place exists on which to test a machine for comfort, as its surface is covered with holes large enough to bury a small football. Yet despite its small tyres and light construction the little F.N. three-wheeler rode those bumps splendidly. Moreover the steering was perfectly steady, and though direct practically irreversible. It is true that to one unaccustomed to use it a tricycle feels somewhat strange, but we can quite understand that such a feeling would pass off in a very short time. We have already referred briefly to the running of the 2¼ h.p. F.N. motor bicycle, and we were particularly pleased to make further acquaintance with it with its tricycle attachment. The particular tricycle in question was fitted with a separate Bowden lever for controlling the clutch—a real and genuine improvement which works admirably. With it the machine may be comfortably started from standstill, and the excellent clutch allows the drive to be taken up with the greatest smoothness. Either by declutching or by raising the exhaust valve the gears engage with absolute ease and silence. Two small points, however, call for criticism. Firstly, the present arrangement of the brakes is capable of improvement. On the tricycle under consideration, there was a back pedalling band brake and a hand operated horseshoe brake. The former we understand will be worked by a pedal. This will be a step in the right direction, but inasmuch as two brakes will still be operating on the same wheel, we venture to suggest that good, well-compensated front wheel brakes would be desirable, and each set of brakes should be worked by pedals placed on either side of the well sprung footrests. Secondly, since it is somewhat difficult to make the engine run slowly when in neutral, a magneto spark advance would be a desirable fitment. In our opinion these two items would tend to render the F.N. tricycle as near perfection as the mind of man can conceive.

The articles in *The Motor Cycle* on multi-point ignition have excited extraordinary interest in this important question, so much so that Lodge Bros. and Co., Birmingham, request us to give prominence to the fact that they cannot accept any more orders for Lodge Double Pole plugs at present, as their stock has been entirely exhausted. By the way, we may inform our readers that these double pole plugs will not fit all makes of engines until the valve caps are altered, on account of the fact that the electrodes project about 1in. into the cylinder.

OCCASIONAL COMMENTS.

BY "IXION."

Coaster Hubs and a Heckler.

I have often felt sorry for political notabilities, when some ingenious heckler unearths contradictory extracts from speeches they have made at varying intervals, and exhibits them as, for instance, cursing Tariff Reform in 1906 and adoring it in 1909. I am now in the same boat, for a correspondent convicts me of slanging coaster hubs for motor cycle work not so very long ago, and then belauding them in a recent issue. I plead guilty. I am not ashamed to change minor opinions when due cause is shown. My own experiences with coaster hubs date a long way back, when these hubs were not a hundredth part as good as they are now; but of late years the experience of others, coupled with examination of the splendidly made hubs now marketed, has led me to revise ancient prejudices. I still prefer the foolproof belt rim shoe, but on chain-driven machines this brake is often impracticable; and, failing the belt rim shoe, I doubt if there is a better substitute than a first-rate modern coaster hub, which, after all, is only a miniature replica of the internal expanding brake in use on most modern cars.

Bravo the A.C.U.

The A.C.U. has at last adopted an ancient suggestion of mine, and fixed up the dates of its principal trials fine and early. This is as it ought always to have been. But is it ungenerous of me to wonder why the principal event of all, the 1,000 miles trial, is always held in July? I admit that month secures a good entry, and is probably the best suited to the trade element. But I thought we had agreed on the principle that trials are to be amateurised as far as possible, and undoubtedly August is the normal amateur's holiday time. I have met lots of riders who bemoaned the July trial, because they could not ride in that month, and it might not be a bad plan to see what entries would be received if the date were August.

The Twisted Belt on Lightweights.

I see Mr. De Lissa takes exception to my remarks on the round twisted leather belt, and says that if riders would only give these belts as much attention as they give their boots, all would be well. But my standpoint is that I object to giving a belt anything like the attention I give my boots. My boots have to be cleaned every day, and sometimes twice a day; they have to be very carefully dried and scraped and greased whenever they get muddy and sodden. If I could get a pair of boots that I could walk in from 1,500 to 2,000 miles with no other attention than the waste of a few minutes three times or so in that distance, I should not wear the sort of boots I wear now.

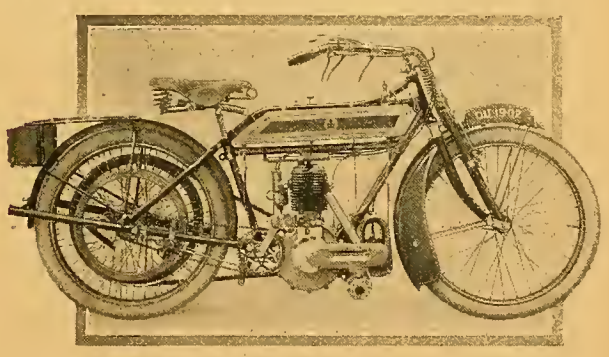
Returning to the sphere of belts, there actually are belts in existence which can be relied upon to propel a motor bicycle for 1,500 to 2,000 miles with no other attention than two or three shortenings, and this is why I and some others I know are not enamoured of the twisted leather variety; though, in fairness to Mr. De Lissa, I must admit these belts give less trouble on the Motosacoche than on any other motor bicycle past, present, or—possibly—to come, thanks to its low power and light weight.

The 1910 Six Days' Trial.

The new regulations for the Six Days' Trial are of exceptional interest. The End-to-end course is not considered severe enough to eliminate the duds among modern motor cycles. It is not possible to construct artificial gradients, and so the trial is to be stiffened by lengthening the daily runs to such a degree that the riders will reach the far north in about five days, and on the sixth day return a decent distance south again for the conclusion of the trial. If they encounter such wind and weather as greeted them up north two years ago, the trial will be stiff enough in all conscience. I should like to suggest a big open hill-climb on Amulree on the following Monday or Tuesday, which I feel sure would be extremely popular. In fact, as the classic course possesses only a sentimental interest, and loses that interest when riders are not out for record, I should like to see the trials make a *détour* and include Amulree in the official route. A motor cycle that can climb Amulree can climb anything, and what a chance for the variable speeders to show what they can do in the way of negotiating steep ascents and bad corners.

A Hill-climb Suggestion.

Now that hill-climbs are so common, the novelty of the spectacle they provide has largely vanished, and it no longer thrills us to see a crouching rider of a motor cycle flit past in a cloud of dust and glory. Hills with difficult and dangerous bends still stir the nerves of the most *blasé*, but as spectacles hill-climbs have lost a lot



A 1910 model Rex. This mount has a 3½ h.p. single cylinder engine, spring seat and spring forks, and a multiple plate clutch neatly disposed in the rear hub, and operated by a Bowden lever on the handle-bar. The foot brake actuates on the dummy belt rim.

of their interest. One of the provincial clubs made an interesting departure last summer in the interests of the spectators by selecting a straight, broad road of moderately easy gradient, and sending the riders up in pairs. I think this method merits a wider application. It might be added to a programme as the last event of the day, riders being handicapped on their previous solo performances, and then to conclude the event by riding against each other in pairs on the knock-out principle, each receiving a start of so many seconds determined by the speed of his earlier ascent. An ideal venue for a trial of this sort would consist of a hill resembling Dashwood, on some lonely road, supposing such a hill exists.

INDIA, the home of the ox-waggon, or, as it is termed in the vernacular, "bile-gharri," is scarcely an ideal country for a motor cycle, nevertheless it is possible to obtain both pleasure and excitement from the possession and use of one. It must be recognised that this is not a country of perfect roads, even in the large cities. The constant traffic of the "bile-gharries," laden with cotton, wears out and renders the best made roads more like ploughed fields than good motor cycling roads. Then add to this the monsoon weather, and you have the most lovely examples of mud rivulets that you can imagine, even if you have had occasion to ride on an English road made sodden by a thaw after a heavy fall of snow. Outside the bounds of cities, during the best weather, some of the roads are not bad, but here and there one finds patches which would call forth sulphurous epithets from a sweet-tempered angel.

I am about to tell you of a little week-end trip which a friend and I planned and eventually carried out, but if any of the incidents I relate do not strike you as being exactly "according to the book," please accept my apologies for "needs must when the devil drives."

The Start.

My friend and I left Bombay one Friday morning during the dry season, having as our destination Igatpuri, a small town about 105 miles away, on the main road to Nasik, a place of great repute among Brahmins. He was mounted on a 3½ h.p. Rex of somewhat early build, and I on my newly imported 1909 Triumph. Laden with a good supply of spares and enough wearing apparel for necessary changes, we felt quite happy as we tootled out of Bombay on to the Thana road. This we negotiated satisfactorily until we reached Kurla, a village boasting of a couple of silk mills, but whose roads were more like dust heaps than billiard tables. Here we crossed the main line of the Great Indian Peninsula Railway, and after passing two small villages turned to the right, and safely reached Thana, where a halt was called at the dak-bungalow for breakfast. What is a dak-bungalow? I hear someone ask.

In a Dak-bungalow.

Well, it is a kind of public hostel under Government control. It is more like a two-roomed hovel, whitewashed inside, with a verandah running round the outside. Here one can get meals of a kind and at a price, and, if desired, sleep on a bed in the same room. Our speedometers at this point registered twenty-seven miles. Getting away from Thana, we again crossed the railway line, and, increasing speed, we had safely covered a couple of miles when the first mishap took place. My friend when travelling at thirty-five miles an hour, badly punctured his back tyre, and so great was the velocity and so serious the puncture that the rim was badly dented. Dismounting, we found it necessary to detach the back wheel and hammer out the rim. This done and the tyre repaired, after a delay of two and a half hours we restarted, and met with a stretch of road practically impassable on account of the depth of dust, but after slight delay we reached Kalyan, our chosen resting place for tiffin (lunch). So far we had travelled forty-two miles only. After light refreshment, of which we felt sorely in need after our exertions in repairing the tyre, we remounted, and, proceeding about one mile, we reached a spot where the sea has forced its way inland, forming a creek of no mean size.

Here it was necessary to enlist the aid of a boatman, and so one by one we crossed the water, each looking after his own machine during the passage. Safely we reached the further bank, but not without some trepidation, as the boat was in some danger of capsizing on account of the unequal weight of the machine.

Away once again, we encountered a piece of road which agitated our "innards" very considerably, for the past monsoon had swept across the road, washing it away, until it had the appearance of a dried-up river bed. To prevent total extinction of the road, square stones had been laid down without mathematical precision; the result was that our bicycles bounded along rather than ran. Hereabouts a further slight mishap overtook my friend, for with continually raising the exhaust the lifter wire broke, necessitating another delay; but, finding we could not repair this, we proceeded under difficulties.

The Result of Riding with a Broken Lifter.

For some miles we were favoured with a good road, and merrily "sailed" along, until we came to several sharp turns, which, trying to negotiate with a broken exhaust wire, my friend found most difficult, and eventually, skidding in a heap of dust, his machine

A Week-end Trip in India.—

turned a complete somersault. Picking himself up, we proceeded onwards, arriving at the foot of the "ghauts" (hills) outside Igatpuri. Here we were temporarily beaten, for it was growing dark, and my friend on examination found that the spill had robbed him of his lamp and toolbag, and in addition we were parched with thirst. To alleviate our thirst we opened my acetylene lamp and drank what water there was in it. Fearing to climb the ghauts in the darkness without a valve lifter, my friend decided to remain while I went forward for help.

Reaching Igatpuri, I called at the Co-operative Stores for a bottle of Pilsener beer, which quickly disappeared. Obtaining possession of a bottle of soda water, I turned back to assist my friend, but after riding a back trail for ten miles I failed to find him, and decided to return to Igatpuri, where I discovered that he had arrived by a short cut over the fields, leaving his machine behind on the roadside. Proceeding to the dak-bungalow, we were lucky to obtain a room just vacated, and after obtaining much needed refreshment we speedily sought the nocturnal couch, and to our weary bodies sweet sleep swiftly came as relief.

Interested natives examining the Rex machine outside the blacksmith's shop at Igatpuri.

A Native Blacksmith's Repair.

Rising betimes in the morning, our first attention was to satiate the demands of "Little Mary." This concluded, we decided to seek my friend's bicycle, which had been left overnight by the roadside. While my friend proceeded in a tonga (a small covered pony vehicle) I mounted my bicycle, and together we reached the spot, to find the bicycle quite safe and untouched. Returning to the village, we sought out a native blacksmith, and managed to get the exhaust wire repaired. The accompanying photograph shows the machine at the blacksmith's shop—an object of wonder and delight to the dark-skinned onlookers. We spent the day alternately exploring the surroundings of the village and resting in the dak-bungalow, where we chatted over our journey with its excitements and mishaps. The following morning we were to return to Bombay, and at 8.30 we were overlooking our machines preparatory to starting, when, much to my friend's annoyance, he found that the fool of a blacksmith had left the exhaust wire too short to give free play to the movement of the handle-bars. On discovering this, he decided to return by rail, and so it remained to me perforce to return alone. Leaving at once, I made a splendid run to the creek, previously mentioned. Obtaining a boatman with a small boat to ferry me across, I discovered, much to my discomfort, that the only money I had was a Rs. 100 note (value £6 13s. 4d.), but on further seach I discovered four one anna stamps (value 4d.), which satisfied the boatman. Having crossed the water, not without a certain amount of danger, I remounted and reached Thana at midday. Here I rested, and later, after partaking of tea, I proceeded on my journey, reaching Bombay without any mishap after an excellent ride, in the cool of the evening. My friend reached home safely, his return trip being accomplished under safer, albeit less exciting, conditions.

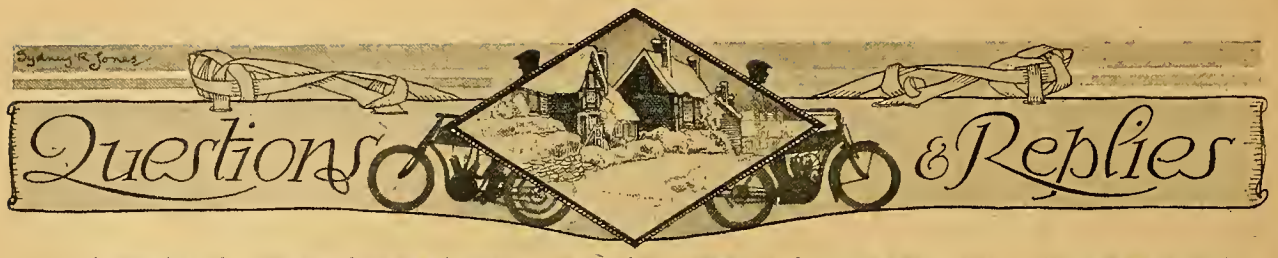
G. H. WILSON.

A Tip for Users of the Mabon Clutch.

MANY readers of *The Motor Cycle* are owners of machines fitted with the Mabon multiple disc clutch, and, like other owners of good things, they often abuse the clutch. I do not propose to tell readers how to keep their clutches in proper order, but rather to call their attention to one tip worth knowing in connection with the operating lever. My remarks apply particularly to machines which have an inverted lever on the left side of the handle-bar for operating valve lifter or brake. With this lever in its usual position the Bowden lever operating the Mabon clutch has, of necessity, to be set more or less horizontally and practically in a line with the handle-bar. In this position one's fingers become cramped when the clutch is continually in use—when driving in congested traffic, for instance. To render the manipulation of the clutch lever a matter of greater ease I moved the inverted lever on my machine further inwards towards the stem, drilling and tapping a fresh hole in the sleeve which fits inside the end of the handle-bar, and using the same screw to fix it. The Bowden operating lever can now be set so that it comes almost immediately under the handle-bar grip and practically in the same position previously occupied by the inverted lever. So placed one can operate the clutch for a long time without cramping the fingers of the left hand. The alteration occurred to me while practising slow riding for the M.C.C. "tortoise" race held at Brooklands last October, and the extra comfort and increased delicacy of control with the lever in its new position astonished me. At first I thought of using the inverted lever for operating the clutch and fitting a small thumb lever for operating the exhaust valve lifter, but the small catch on the thumb lever would possibly be awkward to operate quickly whilst riding, even if it were strong enough to hold up the lever.

H. G. BELL.

When purchasing Rich detachable air tubes riders are advised to see that they get the special lubricant for smearing on the jointed ends as well as an instruction card with every tube, whether fitted to the machine or not. The manufacturers inform us that the tubes are often condemned through these omissions. It is also essential to see that the proper size tube is supplied, as a tube which is too large for the cover can seldom be made airtight.



A selection of questions of general interest received from readers and our replies thereto. All queries should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, E.C., and whether intended for publication or not, **must be accompanied by a stamped addressed envelope for reply.**

Gradient of Westerham Hill.

Having read of tests with motor cycles being made on Westerham Hill, Kent, I should like to know the gradients of this hill.—D. T. (Blackpool).

Westerham Hill, Kent, is 1,764⅓ yards long, lift 392.79 feet, steepest gradient (at the corner) 1 in 7.8, average gradient 1 in 13.44.

Licence for Use of Coupling Attachment.

Please be kind enough to inform me if the Inland Revenue tax will cost me any more if I attach a pedal bicycle to my motor bicycle by means of one of the couplings on the market.—W. Black (Gloucester).

In many districts the authorities insist upon the payment of the two-guinea tax. They consider that a bicycle and motor bicycle when coupled constitute a four-wheeled motor-propelled vehicle. Other authorities are content if a 15s. trailer licence is taken out.

Turning Oil Groove on Engine-shaft.

Would you tell me whether a right or left hand groove should be cut on the shaft of an outside flywheel motor to prevent oil oozing out of the long bearing? Motor revolves in a clockwise direction.—L.L., Perth.

The correct way to cut the spiral groove referred to is the reverse to the way in which the axle revolves.

One Guinea or Fifteen Shillings Licence.

I purchased a motor cycle three weeks ago. Am I compelled to pay 7s. 6d. licence for it this year? I have not taken it on the road yet, but have received a notice calling my attention to the fact that I have not yet taken out a licence for it. Also am I compelled to pay £1 1s. or 15s.—A. D. (Edgbaston).

The Inland Revenue Authorities in their list of exemptions say that a motor bicycle which is kept but not used in any one year is not liable to licence duty. Now, however, there seems to be a little doubt about this (see *The Motor Cycle*, October 13th, 1909). We should advise you to repudiate the liability, and if the authorities are still persistent, either place the matter in the hands of a solicitor, or communicate with the Legal Departments of the Auto Cycle Union, 18, Down Street, Piccadilly, W., and the Motor Union, Caxton House, Westminster, W. The licence payable at present is 15s., and we advise you to apply for it at once.

Gear Ratio for Sidecar Use.

The makers of the P. and M. fit two different gear ratios to their standard machines, viz., for solo work 4½ to 1 and 8 to 1, for passenger work 5 to 1 and 9 to 1. I want a machine that will travel fast for long distance journeys as a solo machine, but shall want to use the same occasionally for a sidecar, and I am in doubt which set of gear ratios to order. Would the 4½ to 1 gear be too high for a sidecar on ordinary roads when I should have the lower gear of 8 to 1 to fall back upon?—Chain Drive.

You cannot have a high gear ratio for travelling fast when the machine is used as a solo machine, and a low gear ratio for sidecar work unless you are willing to alter the chain sprockets every time you use the machine for one purpose or the other. You will have to be content with the low gear ratio for passenger work, and will probably find that with 5 to 1 you will obtain a fair average speed. The gear of 4½ to 1 would be too high for sidecar work on ordinary roads, as though you have the lower gear to fall back upon you would probably require to use it too often, and would find it irksome. That is the reason the makers fit a moderately high top gear ratio.

The Care of Belts. Loss of Compression. Lubrication.

(1.) A few weeks ago I got a ⅞in. Whittle belt for my 3½ h.p. 1908 Tourist Rex (which has covered 6,000 miles). The first day out I ran about ten miles in a downpour with inches of mud and slush on the road, and the belt never slipped. The next two days it slipped badly, although the roads were fairly dry. I am told now that I should have steeped the belt in castor oil before using it, but the makers told me I needed no oil. I put, however, a smearing of engine oil along the upper side of belt before putting it on, for that wet run, and I'm just wondering now whether that is the reason the belt seemed to be very greasy along its sides and picked up a lot of grit. I have now got a tin of special dressing from the makers. I have to ride every day and in all weathers. (2.) My engine will hold my weight (eleven stones) on compression only about seven or eight seconds. I fitted new piston rings only a few days ago and ground in valves and fitted new washers. Do you think it would be advisable for me to get my cylinder reground or rebored? (3.) Do you think I could use Price's C (water-cooled) oil for winter work? (4.) Do you think the amount of oil supplied to engine could affect the noise of exhaust if I use a superfluity of oil? My engine runs almost silently. The less oil there is in crankcase the noisier becomes the exhaust.—D. Patrick.

(1.) After using your belt you should have wiped it or scraped it, removing all grit. Afterwards it would have been advisable to have dressed it with the maker's dressing or collan oil. Possibly the cause of the trouble is that the grit on the belt caused the surfaces of the leather links of the latter to become shiny, and that you dressed this with oil of an unsuitable nature without previously removing the grit. (2.) If you only fitted new piston rings a few days ago you must allow a short time for these to become properly run in. Probably after you have done 300 or 400 miles the compression will return. (3.) The oil would be quite suitable. (4.) Yes, certainly an excess of oil will make the engine run quietly, but it tends to foul the engine. The makers of your engine now fit an automatic lubricator which you could doubtless obtain.

Fitting a Free Engine Clutch.

(1.) Could a Mabon, L.M.C., or other free engine clutch be fitted to a 1909 machine which has no provision for a clutch? (2.) Will a clutch allow one to start the machine from a standstill? (3.) Could I fit it myself? (4.) Is it injurious to the engine to inject large quantities of petrol through compression tap? Will a clutch allow one to start the machine on a fairly steep gradient with single gear?—D. G. A. (Newcastle-on-Tyne).

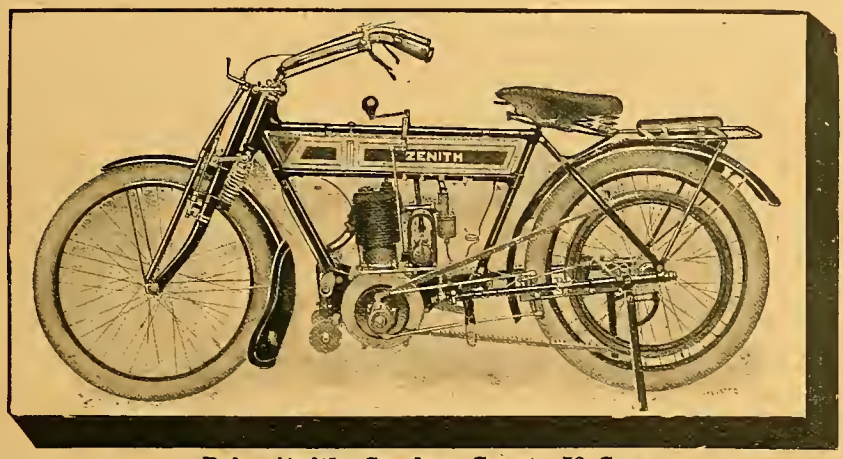
(1.) Most 1909 machines are suitable for the Mabon, L.M.C., or other clutch fitting on engine-shaft. A clutch in the back hub might entail some structural alterations. (2.) If carefully manipulated a clutch would allow you to start from a standstill. (3.) Not unless you are a fairly experienced amateur mechanic. (4.) Certainly, it is injurious if overdone, as it tends to wash away the lubricant from the piston rings. Paraffin or petrol can be recommended, but there is no necessity to use a large quantity. (5.) If the machine is geared low, with careful manipulation it is possible to start on a fairly steep gradient.

ZENITH-GRADUA

Mr. B. H. Davies' Opinion—

"The 1910 Zenith will be as great a terror on hills as its 1909 prototype, and, in addition, is transformed into one of the prettiest mounts on the road. HATS OFF TO A GENUINE ALL-WEATHER TOURIST MACHINE."

Zenette Spring Frame (Patent), 6 Gns. extra.



Triumph Conversions 12 Gns.

Machines must be sent to our Works.

Price (with Gradua Gear), 52 Gns.

Speed Against the Wind.

The questions below refer to Phelon and Moore 2½ h.p. 125 lbs. two-speed lightweight. (1.) What is the length of Netherhall Gardens and the gradients? (2.) What speed ought an eleven stone rider to get out of above machine on an ideal day and on a windy day? (3.) What gradients could an eleven stone rider climb on the above-mentioned days? The P. and M. people say that it will climb Netherhall Gardens and do a speed of thirty-five miles per hour, but what is the weight of rider, etc., for such a performance?—H. H.

(1.) The total length of Netherhall Gardens is 993 yards, and the principal rise occupies about 602 yards. The steepest portion is 1 in 7.2, followed by gradients of 1 in 10, 1 in 15, then level, and then slightly downhill. (2.) There would be a difference of about three miles an hour on a windy day from what there would be on a calm day. (3.) On the low gear it would not make much difference. You can probably rely upon climbing 1 in 7 under practically all conditions provided your weight does not exceed eleven stones. The maker's estimate is about right if the rider weighs about eleven stones.

Misfiring and Running in Jerks.

Please advise me as to what is wrong with my 3 h.p. N.S.U. The machine has coil and accumulator ignition, and is running badly, missing fire and running in jerks, and refuses to get up any speed or develop any power when on the road. If I run it on the stand, with the rod operating the inlet valve disconnected, *i.e.*, with the inlet valve working automatically, it runs well; but if I try it on the road with automatic inlet valve it runs badly, and on the road or on the stand with valve working mechanically it also runs badly. There is a distinct blow back into the carburetter. At first I thought that the inlet valve was not shutting properly, but I examined it, and as far as I can see it is all right. The ignition is in good order. I can see no solution to the trouble, which seems to me to lie either in the valve or the carburetter. Could the timing gear be wrong by any chance?—TUATH MUMHAN.

We should recommend you to dismount the inlet valve, its seating, and operating mechanism, and examine all the parts very carefully, as some defect in this is almost certain to be the cause of the trouble. Probably, we should imagine, the spring is too weak, and a stronger spring may be necessary. The blow back to the carburetter seems to point to the inlet valve opening too much. Note that there is only sufficient clearance between the tappet and valve stem to insert a visiting card, and see that the opening occurs at the proper time. Excessive wear in the cams and tappets or any defect in the timing gear would account for the symptoms you describe. The amount of valve lift is adjustable.

Touring Abroad.

I am starting in a week's time for a three weeks' tour to the South of France. Is it necessary to have my machine "examined" and to "declare" it before the officials at Calais where I start? Will it be necessary to get new registration numbers, or will the English number be sufficient? Is a driver's licence needed? If needed how can it be obtained without delay? Is motor cycling practicable in Greece, Egypt, India, and the East Coast of China? I shall be going to these countries and wish to take my motor bicycle with me if petrol can be had on the main roads, and if these roads are fair.—B.J.H.

First of all it would be advisable for you to join one of the motoring organisations, either the Auto Cycle Union or the Motor Union. You will find that it will simplify matters for you to an extraordinary extent. Membership allows you to get a vast amount of information regarding touring abroad free of charge, and you may purchase your tickets beforehand and have your route mapped out; also get a Customs ticket which will admit your machine into the country free of duty. It will be necessary to register the machine in France, which will cost about sixty centimes, but you may if you like carry your English numbers. The bodies in question will also tell you if motor cycling is practicable in Greece. In Egypt, India, and in parts of China it is possible. It may be necessary to obtain a driving licence in some of the countries named, but not in France for a short stay.

Increasing Power and Silencer Explosions.

(1.) Can I get more power for hill-climbing with sidecar out of my 3½ h.p. Minerva by making extra holes in jet of Longuemare carburetter? (2.) How can I stop the banging or loud explosions in the silencer every time I lift the exhaust valve? I have put new valves in the engine, and it is now worse. It is a very objectionable noise when there is much traffic. —F. C.

(1.) You can get more power by enlarging the jet of your carburetter, but if the carburetter is apparently adjusted satisfactorily at present and the machine runs well and keeps cool, it is wise not to interfere with it. A larger jet will necessitate enlarging the extra air supply or fitting a larger choke tube. If you overdo the size of the jet the engine will quickly overheat. (2.) You can stop the explosions in the silencer by fitting a switch and switching off before you raise the exhaust valve. Also make sure that your exhaust valve lifter is working properly. If you do not desire to fit a switch, try controlling speed by the throttle lever, and always close the throttle before raising the exhaust valve.

Of lawn tennis fame. Mr. G. W. Hillyard, of Thorpe Satchville, Melton Mowbray. His mount is a free engine Triumph.

THE SHOW QUESTION

The Amateur Motor Cyclist's View.

BY "AUTO-KUKLOS."

ON more than one occasion the amateur motor cyclist has rightly been called the most enthusiastic of all motorists, and consequently he is extremely critical about the way the machines in which he is so deeply interested are displayed at different exhibitions. When he visits the annual show at which his beloved motor bicycle may only be seen, he is annoyed by having complete pedal bicycles, and numberless stands of pedal cycle accessories, many of which are for the trade only, meeting him at every turn. It has been said the pedal cyclist is the man who fills the ranks of motor cyclists, and in a sense this is true, but it is doubtful if many converts are obtained among the class of man who belongs to the type of cycling club whose members take up the best part of the highway near our large cities on a Sunday morning. This class of man, who usually predominates among the throng at the cycle show on Saturday evenings, has generally neither the money nor the inclination to buy a motor bicycle, and it is doubtful if from this type many motor cyclists are gained. No, it is from the slightly wealthier classes that most recruits come—men who love their steeds, who are devotees of the mechanical, and when once won over are the most enthusiastic of enthusiasts. Naturally these people were once owners of pedal bicycles (and many still own them and use them for short town journeys), but they merely rode them while they awaited the coming of some better means of locomotion, or a congenial motor cyclist to convince them of the advantages of the motor cycle. These seventy odd thousand motor cycle users, many of whose letters pour in their hundreds to the Editor weekly, want something different in the way of shows than they have had in the past.

A Purely Motor Cycle Show.

Indications are clearly seen that what they desire most, and for which they clamour, is a purely motor cycle show, or a thoroughly representative motor cycle section of a motor show, and they are not anxious to go to a second-rate district of London to see it. Now I will ask the kind permission of the Editor to enquire of the readers of *The Motor Cycle*, through the correspondence columns, if they as motor cyclists would rather wade through avenues of pedal-propelled machines and rows of pedal cycle accessory stands, or see their motor cycles and the many interesting accessories appertaining to them ranged together, say, at the Aeroplane Show of the Society of Motor Manufacturers and Traders. There would be room there for an excellent display, and they would be by no means out of place. Again, the complete set of shows could be held simultaneously—motor car, motor cycle, aeronautical, and lastly pedal cycle, in various buildings a few yards apart at the White City.

Though this idea is not original on the part of the writer, he thinks it is worthy of consideration. This suggestion would, at any rate, come very near to the ideal, as it would necessitate all the shows being held together in one week, which would be of enormous advantage to provincial visitors, both amateur and trade. It might also be possible to use the spacious grounds of the White City for trial runs, which were so much appreciated at the Crystal Palace years ago. A certain section of the motor cycle industry, namely, those who form the committee of the newly-founded Association of Motor Cycle Manufacturers and Traders, expressed it to be their firm opinion that a purely motor cycle show was necessary.

A Knotty Problem.

Now my article is intended to appeal to the amateur only, and it is his opinion that I want to get. Nevertheless, though the industry must be considered, it must be left to find out its own solution of the problem. The problem is this: The Stanley Show want to cater for the motor cyclists, and intend to hold another show this year; the Association of Motor Cycle Manufacturers and Traders (and undoubtedly all amateur riders agree with them) want to see a show for motor cycles only; the Society of Motor Manufacturers and Traders want to run a motor cycle section, and would probably establish a motor cycle show in conjunction with their Aeronautical and Motor Boat Show, as suggested above; and the Cycle and Motor Trades' Association want to organise a mixed motor cycle and cycle show at Olympia. Here is a pretty tangle. One show and one show only must be supported, but the motor cyclist, whose numbers are increasing, wants the motor cycle industry to be properly and adequately represented.

It has been suggested that an exhibition of motor cycles only could well be held in such a compact and easily accessible place as the Horticultural Hall, Westminster, which would probably accommodate the trade in its present state, and this the writer would gladly welcome, but it must be borne in mind that the industry, though vigorous, is young, and to those firms who build motor cars, motor cycles, and pedal bicycles, three separate shows would impose a heavy tax on their resources. If the amateur is at all clear as to what he wants, he can use his influence to get it by writing to the Editor of this journal, who has given me permission to say that amateur motor cyclists' suggestions regarding the show question will be willingly inserted as space permits in these columns. In a few months from now things will begin to hum once more, and it is time for action *now*. Therefore let everyone concerned put his whole energy into this important question.

Write for descriptive leaflet.

Foot on pedal and up you go.

Quite simple—just like mounting a bicycle.

Another point—the

SINGER Moto-Velo

is as economical to drive as it is easy to mount. It is a 1¼ h.p. machine and will carry you 140 miles on a single gallon of petrol, at any speed up to 30 miles an hour. If you want to, you can detach the engine—five minutes' work.

A Bosch High Tension Magneto is fitted, and the machine complete weighs only 84 lbs.

Singer & Co. (1909), Ltd., Coventry. **London Depot: 17, Holborn Viaduct, E.C.**

THE BAT SPRING FRAME AND FORKS.

THE MOST COMFORTABLE MOTOR CYCLE IN THE WORLD.

FITTED WITH

SPRING FRAME. The rider being suspended on springs no vibration can possibly reach him, no power is lost in transmission, a rigid connection being maintained between engine and back wheel. A perfect sitting posture, natural and untiring—**as fitted for the past eight years.**

SPRING FORKS. Mounted on ball bearings, overcoming all obstacles in an even and vibrationless manner—**as fitted for the past five years.**

J.A.P. ENGINES. The acknowledged perfectly designed and finished engine, and proved fastest and most powerful—**as fitted for the past five years.**

AUTOMATIC LUBRICATION. Perfect in action and always to be relied upon. Its requirements are a perfectly fitted crank case to exert the necessary suction (which it has in the J.A.P., and therefore needs no auxiliary oiler). We have fitted this exclusively **for the past four years.**

MAGNETO IGNITION. Bosch ball bearing magneto, fitted in tank, protected from all wet and dirt: driven by bevel gears mounted upon a vertical shaft. A simple and efficient drive, easily adjusted and seldom requiring to be lubricated (the gears running in grease boxes). No complicated drive or inaccessibility. **As fitted for the past four years.**

All machines sent out thoroughly tested, and complete with petrol gauge, stands, large strong luggage carrier with tool box (accessible without disturbing luggage), tools, pump, and clips.

3½-4 h.p. Single-cylinder. 5-6 h.p. Twin-cylinder. 7-8 h.p. Twin-cylinder.

SPEED.

"At the same time it will reach a very high speed, if one is bold enough to let it. I am satisfied with 25 miles per hour.
"M.R.C.S., M.R.C.P."

AUTO-CARRIERS, LTD.,
Martell Road, West Norwood, S.E.

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, E.C., and should be accompanied by the writer's full name and address.

Amulree Hill-climb.

[4473.]—Replying to Mr. Cameron's letter, published on December 13th, he admits that Mr. Campbell McGregor's machine—a T.T. Matchless model—was allowed to compete in the touring class. Why then was Mr. J. Adamson debarred with his 3½ h.p. T.T. Triumph? The two machines are the same in detail, allowing for each maker's ideas, with the exception that the 3½ h.p. T.T. Triumph is 10 lbs. heavier and the rider 3 stones heavier. An explanation will oblige.

FAIRPLAY.

English v. French Measurements.

[4474.]—In support of Mr. Scott's contentions with regard to the confusion resulting from the use of millimetres for cylinder dimensions, a very striking example occurs in the article by Mr. Norton on "Bore-stroke Ratio and Efficiency." The writer after launching forth in millimetres finds it convenient suddenly to convert his square centimetres to square inches in order to find the load in lbs. on the bearings of the engine.

If it is necessary to give the cylinder pressures in lbs. per square inch, why give cylinder areas in cubic centimetres?

FRANK PHILIPP.

Does an Engine Run Better at Night?

[4475.]—Some time ago Mr. E. L. Ovington, of New York, raised a discussion in your columns on the "abnormal running" of a high speed air-cooled engine.

There is another abnormal condition resulting in an engine turning over unusually fast and pulling harder, and this generally occurs as night comes on, but occasionally before dusk. For a long time past I have watched this singular condition in a single-cylinder Indian, and also with two other American makes. Some riders say here that one only imagines one is travelling faster at night, but this is not so, for I have watched the behaviour of the engine day and night on familiar hills.

Rainy or damp days do not seem to produce a mixture having a greater expanding force. I would be pleased to hear if any English riders have noticed this kind of abnormal running, and what explanation they have adopted for it, if any? Wishing *The Motor Cycle* every success in the New Year,

EDWARD O. DUNKLEY.

Rhode Island, U.S.

A Friendly Match.

[4476.]—With reference to Mr. H. C. Tromp van Diggelen's letter in the issue of December 20th. As this gentleman still persists in challenging his Wanderer machine against a British machine of higher power, I, for one, should very much like to see the discussion ended, and I should be sorry to think that your readers were gulled into imagining that this new arrival of 2½ h.p. was equivalent to our British machines of 3½ h.p.

According to Mr. Diggelen's statement in his letter, the distance he raced the members of the Western District M.C. was not sufficiently long to give his engine a chance, and so I would like to accommodate him by racing for the distance he suggests, viz., 100 miles, the loser to pay track expenses. My machine is a 3½ h.p. Brough standard touring model (which can be proved in a tortoise race afterwards).

Mr. Van Diggelen also says in his letter that he has no interest whatever in the Wanderer firm. If this is so, why was he, on the occasion of the M.C.C. meet at Brooklands, showing photographs of the various models made by this firm, and informing people that he had introduced the Wanderer into England?

GEO. BROUGH.

Wired v. Beaded Edge Tyres.

[4477.]—I have read with interest the letters on wired *v.* beaded edge tyres, and I think that the greatest pull that the beaded edge has over the wired has not been mentioned. I mean that of friction between cover and rim, which has caused me endless trouble with wired edge covers, but I have not had a single instance with beaded edge. Also I find that the beaded edge keeps out the water much better than the wired, and the air tube does not deteriorate with rust from the rim (inside cover) as does the wired edge. I have had ten years' experience of wired edge, and do not want another.

G. LOBB.

Two-speed Gears.

[4478.]—It may interest the patentees of the two-speed gear (patent No. 24,729, 1908) illustrated under recent patents, page 1018, December 20th, 1909, to know that I took out a provisional specification for the same idea some years ago, but owing to there having been prior use on the public highway it was useless my obtaining a complete specification. The details and description of this gear were illustrated and described in this journal on June 20th, 1904, pages 588 and 589. I have had it in operation on my tricycle some four or five years with complete success, it having run some 10,000 miles, during which time I have had not a single thing go wrong with it.

I write this because it may save the patentees time and money, as I was bitten by the same thing.

LEONARD R. JONES.

Cold Fingers.

[4479.]—As an all-weather-200-mile-per-week-every-week motor cyclist (in the course of my professional duties as a road surveyor and lecturer at evening classes in various centres in different parts of Cheshire), I am naturally very interested in the correspondence *re* cold fingers which appeared recently in *The Motor Cycle*. I have tried practically all forms of covering, and find that a good pair of loose fitting woollen gloves covered over with a pair of large (size 9) leather hunting gloves makes as effectual a protection as anything. The chief point, to my mind, is that wool should be fairly loose—I mean not tight fitting—to allow free circulation. I am never troubled with cold now, although I am out riding some four nights per week and every day during the winter.

F. J. K. C.

Possibilities of a Modern Tricycle.

[4480.]—Having read "Ixion's" comment regarding the probabilities of a modern tricycle, and having myself experienced the instinct to balance and steer with the front wheel of the tricycle, I think the trouble might be done away with by having wheel steering fitted, and perhaps a bucket seat. These (especially the former attachment) should, I think, remove the difficulty, as they give you the idea of being on a non-balancing machine, such as a car. I should like to know what "Ixion" thinks of the idea?

R. OVERMAN.

[4481.]—In the issue of December 20th the "Possibilities of a Modern Tricycle" forms the text of some remarks by your usually prescient writer "Ixion." I have read the article carefully through, and fail to find any possibilities described, save that of the certainty of accident, and the dogmatic opinion that when the tricycle is so arranged that two wheels are steering in front and the third is driving

behind, then it is very miserable to sit upon. Having given much attention to the problem of constructing a satisfactory motor tricycle, and having ridden one for the past three years, in which I steered with the two front wheels and sat over the driving wheel at the rear, and found the same very satisfactory, especially from the point of perfect and almost unconscious steering and general comfort in riding, I feel constrained, if you will allow me, to correct the very false predictions in the article alluded to.

The first thing to note is that a tricycle is steered and not balanced, and that the arrangement of two front wheels with Ackermann axles (the ordinary motor car method) gives far more steering power than can be obtained if there be only one wheel in front. As most of the weight is behind the front axis, there is a real tendency for its inertia to find support and bearing on the front wheels, which gives a sense of security, especially at fast speeds. This is not present with a single front steering wheel, which is liable to be deflected by ruts in the road.

A very essential thing in a tricycle is to keep down the weight. It leads to less first cost, to economy in tyres, handiness, a long mileage to the gallon of petrol, and to all-round efficiency. Now the weight is very materially reduced

Familiar faces on the Sevenoaks Road at week-ends—Mr. and Mrs. W. J. Leader on their 5 h.p. twin-cylinder Kerry with Liberty sidecar. The sum total of stops, beyond trivial adjustments, on the above combination during 1909, were one puncture to sidecar tyre, and one stop due to mishap with the timing gear. The machine has now run 3,770 miles with 22½ stones up. Mr. Leader speaks well of the Peter Union bands on the tyres.

by having to drive only one wheel. To drive two wheels through a differential and to have at the same time a two-speed gear makes a difference of at least 50 lbs. in weight and £20 extra in cost.

The great bugbear in all motor cycle touring is where is the luggage to go. The difficulty is solved with the two front wheels, for, as "Ixion" remarks, weight placed over the front axle adds to the stability.

It is a universal experience with tricycles, motor and otherwise, that in turning corners one must go slowly. Sitting over the back wheel there is more space and greater freedom to lean the weight of the body inside the curve one may be turning, by standing on the inside pedal. This action, I may say, becomes almost automatic and unconscious with experience.

I think a two-speed gear absolutely essential to a motor tricycle, and I look forward in the near future, now that many excellent engines of quite moderate power with smooth and quiet working two-speed gears have been evolved, to see motor tricycles again upon the road, providing a most comfortable mount to those of the older brigade who have passed through and beyond the joys of the single track machine.

BERTRAM CHATTERTON.

Motor Cycle Tyres.

[4482.]—Motor cycles are becoming almost too reliable—and complicated. What we really want is simplicity, yet that seems just the last aim of the modern manufacturer. And what a time we still have with tyres! Year after year tyres become more expensive and go to pieces quicker. One make goes at the bead, another in the centre of the tread, and on a third the canvas parts company with the rubber all the way round the tyre. And the tyre companies behave so peculiarly. One friend of mine sent a tyre, through an agent, to a well-known firm to be retreaded. They replied that the tyre was not worth it. Since then he has been trying ineffectively for three months to get his tyre back. Another company had a pair of faulty tyres returned to them, repaired one under guarantee, but refused to repair the other, though both were of the same age and suffering from the same fault, and what is still more remarkable, they removed their trademarks from both tyres. What was their idea in this? What we want in Scotland is a tyre that will last on our roads. Such a tyre, apparently, is non-existent. When will all tyre companies fit a valve to their inner tubes that will hold air without having to be pumped board hard?

TYRED.

The A.C.U. and Provincial Clubs.

[4483.]—I have been very interested in the two letters which have appeared in *The Motor Cycle re* the A.C.U. and provincial clubs. I should be very sorry indeed to see a split in the governing body, but I am very much afraid that unless the A.C.U. alters its tactics and caters for the provincial clubs a little better there is bound to be one.

I fully agree with Messrs. Brook and Smith that the council meetings should be held consecutively in different towns, although instead of Gloucester, as Mr. Brook suggests, I should certainly say Birmingham or Coventry.

I think No. 5 proposal in Mr. Brooks's letter is a very good one. It is simply ridiculous that two or three clubs cannot have a friendly competition without having to pay for a special permit.

And why should every competitor in such an event have to pay 2s. 6d. for a racing licence?

I am sure some of the quarterly trials and long-distance competitions (I don't say all, but just one or two of them) ought to start and finish in the provinces. It seems to me that the provincial members are the "mugs" who help to provide the necessary for the metropolitan members to buy cups, etc., for the Londoners to compete for.

I hope that some arrangement will soon be arrived at which will bring the provincial members on level terms with the metropolitan members.

HOWARD R. LANE.
Hon. Sec. Sutton Coldfield Automobile Club.

Belts on Lightweights.

[4484.]—"Ex-lightweight's" remarks *re* belts on lightweights seem to me to be the outcome of gross misuse of the belt in question. My Motosacoche round twisted belt, as supplied by makers, has given me no trouble whatsoever. Mr. De Lissa's remarks are quite in accordance with facts.

My advice to lightweight riders who use round twisted belts is:

1. Get a good one (a double ply).
2. Keep it as slack as possible without slipping when running.
3. Don't use it when dirty, but clean it.
4. Use it alternately with a spare, so that when it has been running some time it can have a rest.

My own practice is to keep three belts, using them every alternate week, thus each belt gets a fortnight's rest, which seems to restore its elasticity, and there is no undue wear.

My oldest belt has been running eighteen months in this fashion, and seems good for many miles yet. Naturally, it is rather thin, but when well dressed it pulls as well as ever.

A V belt on a lightweight under 2 h.p. is unnecessary, and absorbs too much power in transmission, and is not nearly so satisfactory as a round one with jockey pulley, as proper tension is a *sine quâ non*.

"Ixion's" remarks are useless and misleading, as they only apply to the old "crock days." Let him ride a Motosacoche with a round twisted belt of best quality and then his criticisms may possibly be of some value.

G. E. CASE MORRIS.

Bore-stroke Ratio and Efficiency.

[4485.]—I was very interested in Mr. J. L. Norton's article on "Bore-stroke Ratio and Efficiency," but on carefully looking into the figures given there appear to be several serious discrepancies which render absurd and modify some of his arguments in favour of long stroke engines.

First of all, in considering heat losses through the area exposed to gases, Mr. Norton finds that, with the exhaust valve opening at 85% of the downward stroke the short stroke engine has 23 square centimetres more area exposed than the long stroke.

On checking over the calculations, I find the total area exposed in the case of the short stroke is 377 square centimetres, and in the case of the long stroke 376.6 square centimetres. The difference in areas is therefore negligible, and the only thermal efficiency argument rendered futile.

Another point which is not quite clear is the statement that, "considering the valve pockets, a long stroke engine shows a higher thermal efficiency than a short stroke engine."

Again, on considering the stress on bearings, the area of the small diameter piston is given as 7.5 square inches, which under a load of 150 lbs. per square inch gives a total load on the connecting rod bearing at dead centre of 1,100 lbs. Then, for comparison, the area of the large piston is given as 19 square inches! the total load in this case being quoted as 2,800 lbs. In reality, this would be 12 square inches and the load 1,800 lbs.

Also considering stress on bearings, it is stated that to obtain equal power from both engines it will be necessary to run the short stroke engine at a higher speed. At the commencement of the article, power is said to be governed by piston displacement (compressions being equal), and also that the two engines under consideration are of equal piston displacement, therefore, it follows that both engines to give the same power must, obviously, run at the same number of revolutions per minute.

With this in mind, the short stroke engine does not suffer from the thermal and frictional disadvantages that the author would have us believe; in fact, the number of strokes per minute, being of necessity the same in both engines for the same power, the long stroke engine is labouring under the same difficulties of induction and exhaust (dealt with at some length by Mr. Norton) as the short stroke engine.

I am pleased to see that Mr. Norton graciously admits that the short stroke engine gives greater power per unit of engine weight than the long stroke—a very desirable feature in motor cycle engines. J. T. CLARKE.

[A copy of the above letter was submitted to our contributor, Mr. J. L. Norton, whose reply is reprinted below.—ED.]

[4486.]—I thank your correspondent for calling attention to the discrepancies in figures in my article, due to my having been given a misreading of the slide-rule. The difference in total area exposed should be .4 square centimetre, and not 23; but I cannot agree with his assumption that the correction of figures disposes of the matter of the higher efficiency of the long stroke.

Total area was *finally* considered for the sake of brevity, but when your correspondent says that "the only thermal efficiency argument is rendered futile," and later "the short stroke engine does not suffer from the thermal . . . disadvantages the author would have us believe," I must with all courtesy suggest that he has not read the article with sufficient care or thought to prevent his overlooking consideration of factors of vital importance to the question. As a matter of fact, the disadvantages are very considerably greater than even the surplus figures tended to show; and I would call his attention to the area and shape of combustion chamber, and, further, to the following factors affecting thermal efficiency:

(1.) Heat loss depends upon temperature difference.

(2.) Period of greatest thermal loss is the period of greatest pressure or heat.

(3.) Conductivity of gas increases rapidly with temperature, and makes heat-loss at high temperatures much greater than in simple proportion to temperature.

(4.) Heat loss varies as the ratio of surface to volume.

(5.) The most important losses are those during ignition, as they affect the whole of the stroke, lowering mean pressure.

(6.) Surface of the combustion chamber and valve pocket area exposed during the whole time occupied by the stroke, the stroke walls being exposed during part of the stroke only, and to comparatively lower temperature.

(7.) Shape of combustion chamber materially affects efficiency, a compact form tending to higher mean pressure, greater economy, and therefore also higher thermal efficiency.

Bearing above paragraphs in mind, a little consideration will show the superiority in point of thermal efficiency of the long over the short stroke, which latter presents approximately twenty-five per cent. more cooling area to the gases when their temperature and conductivity is highest, and at a period when loss affects the whole of the subsequent stroke.

I need not dilate further upon this.

Your correspondent says another point not quite clear is the statement that "considering the valve pockets, a long stroke engine shows a higher thermal efficiency than a short stroke."

My statement was based on the assumption that valve dimensions are proportionate to piston area. Larger valves require larger pockets, with necessarily increased area exposed (see paragraphs 2, 4, and 6 above).

Considering stress on bearings, apart from thermal losses, your correspondent is correct in giving the area as 12 square inches, and load 1,800 and not 2,800. This was a typist's error in transcribing from hastily pencilled notes. The percentage of difference in load is 63.5 against the short stroke—not an inconsiderable item, remembering that a variation of the load (load increasing with decrease of stroke) also affects friction.

It is a generally understood fact that a short stroke engine under practically all circumstances suffers from greater mechanical disadvantages than the long stroke.

To deal with that portion of your correspondent's letter commencing "Also considering stress" and ending with the paragraph previous to "The long stroke engine is labouring," I should have to rewrite a portion of the article, and emphasise more clearly the matter of efficient burning, etc., which he has overlooked. May I recommend further perusal of the earlier portion of the article, and also refer him to his figures showing 700 lbs. greater stress on the short stroke bearings?

His statement that a long stroke engine is labouring under the same difficulty of induction and exhaust requires consideration, and does not entirely agree with my deductions. I should be pleased to receive proofs of the correctness of his views.

The matter of bore-stroke ratio and weight is an interesting one, and at first glance appears to open up glorious possibilities to the motor cyclist. It is, however, unfortunate, and must not be overlooked that he cannot with the usual type of engine avail himself of the full advantage of the possibilities of weight saving the short stroke offers him, as may be done in the case of a car engine, and whilst, as your correspondent implies, a light engine is a very desirable feature, it is questionable if it is not better for the motor cyclist to carry a little, a very little, additional weight low down, and ensure efficiency, flexibility, a strongly pulling engine for hill work, and economy, or to take the weight from the engine, place it high up in the tank, with the loss of above advantages, and pay, pay, pay for it.

I look forward with interest to the article by Mr. A. A. Scott, and derive pleasure from the fact that the object of my article is likely to be realised, *i.e.*, profitable discussion, which will tend to the improvement and greater efficiency of the motor cycle engine.

JAS. L. NORTON.

EXPERIENCES WANTED.

"K. K. K." (Bristol) would like readers' experiences with benzine as a fuel.

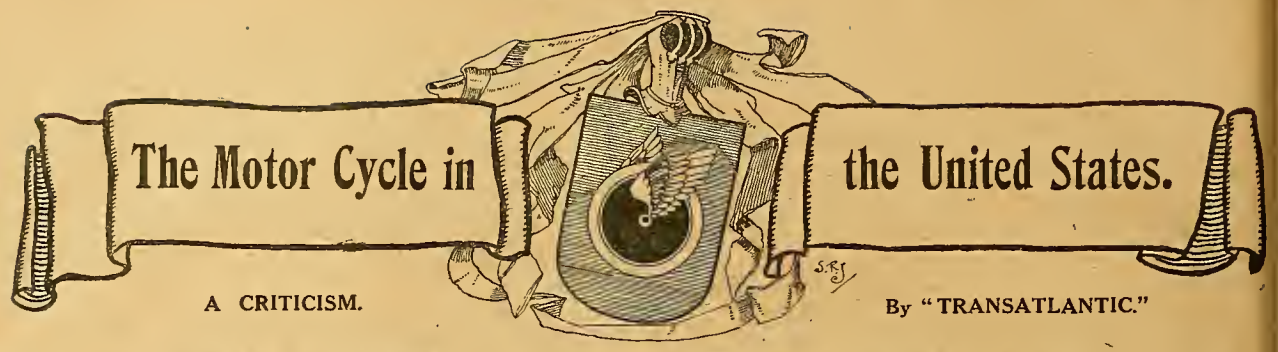
"C. B. A." (Watton) would like readers' experiences of the Hobart Bird Handy lightweight.

"B.L." (Switzerland) would like experiences with A.C. tandem tricars, especially as to rough roads, steadiness of springing, and sufficiency of brake control.

"FC 424" (Bromley) would like private owners' experiences with the Zenith Gradua (4 h.p. J.A.P.), particularly as regards petrol consumption and wear of belt.

"Minerva" (East Ham) desires readers' experiences of a push bicycle coupled to a motor bicycle, especially as regards (1) safety, (2) vibration, (3) negotiating corners, and (4) how and where to fix couplings.

"Opal" (Exmouth) would like readers' experiences of Lomax, Phrax, and Gripstein belting, particularly on 2¾ h.p. twins; also the Service Co.'s mirror lens acetylene searchlight.



The Motor Cycle in the United States.

A CRITICISM.

By "TRANSATLANTIC."

(A friend possessing an inside knowledge of the motor cycle industry has just returned from a lengthy visit to the States, and has given me the following impressions of motor cycles across the herring pond.)

"WHAT do you think of Yankee machines?" was my first question.

"Well, barring the Indian, which you all know, and which is easily the most popular mount in the States, they are, frankly speaking, a disappointing lot—very much where English machines were four or five years ago. Gaudy coloured enamels and ungainly tank and frame outlines are, of course, mere matters of taste, but both in constructional details and general specification they are as a class vastly inferior to British types."

Magnetos Not Standard.

"Very few makers have yet adopted the magneto as standard, though many are ready to fit it as an extra. The automatic inlet valve is still retained on most engines. Luggage carriers are conspicuous by their absence, perhaps owing to the small amount of genuine touring work possible in most localities. Very often no stand is provided, and some of the few stands I saw were worse than useless. No attempt is made to shield the rider from bad weather; even a front mudflap seldom figures on a standard mount.

"The frames almost without exception exhibit marked crudity in design. Bent tubes chiefly predominate, the English plan of reaching a maximum combination of strength and lightness by using straight tubes with struts being almost unknown. The engine is often attached by a light, flimsy clip, and in particular the steering heads are often short and not set at the best steering angle."

American Motor Cycle Engines.

"This is biting criticism indeed. What did you think of their engines?"

"Generally speaking, they are totally devoid of that smart aspect to which we are accustomed in England. They are stuck on the frames rather than built into them, and the exhaust piping is long, thin, and full of bends. Mechanical inlet valves are far from being standard. The carburetter is fitted anywhere—on some machines it is in front of the cylinder, where it gets frozen itself and screens the engine; on others it is at the back, coupled up by a long meandering pipe.

"The control is almost universally by twisting grips with rod or linkshaft connections, and struck me as considerably inferior to our flexible wires, because of the number of joints necessitated in such a system and the rattle and backlash which time is bound to produce in them. Of course, the majority of American makers have never had to cater for reliability in the same sense that our makers regard it, for most of their customers only use their machines for short excursions to suburban resorts, the country roads being so unspeakably vile, while in addition the towns are tremendous distances apart, and intermediate supplies are not obtainable."

The Popularity of Chain Transmission.

"Did you form any opinion about the popularity of the chain drive?"

"It is certainly an easy winner over the belt, but that is simply due to the shoddy nature of most Yankee belts. Many riders told me it was absolutely impossible to obtain a decent belt of American manufacture. I was shown many which were quite worn out after 100 miles, and they cost as much as ours. They are often good for nothing after two or three days' use. Hence the wide popularity of the chain. Many of the chain drives are also very flimsy. Chicago appeared to be the centre of the motor cycle manufacture, many firms having their factories either in the city or in what they would term 'the immediate neighbourhood,' *i.e.*, somewhere within a radius of 400 miles. The suburban roads round Chicago are excellent, but the main street is—with the exception of Montreal—the worst I have ever seen. At the corner of State Street and Jackson Avenue—corresponding, say, to Piccadilly Circus in London—I measured one hole fourteen inches deep. Along such streets as this motor cars run as far as possible on the tram track. Shock absorbers are both universal and indispensable, while ninety per cent. of the cars I saw were run with open exhaust."

Catching Up Quickly.

"Do you think there are any prospects of a general improvement in American motor cycles?"

"Undoubtedly. They are catching up fast, and in two or three years will most probably be as good as ours. Several makers have bought samples of our best machines, and are copying their strong points. I found many makers quite candid in admitting that we were streets ahead of them, and they are beginning to work on our lines. When they have all got hold of magneto ignition, mechanical inlet valves, proper engine attachments, straight tube frames, and reliable belts, which might occur within two years, they will not be far behind. But at present, thanks to their magnificent waterways and execrable roads, the motor boat is considerably more popular than the motor cycle. The American riders are obviously very fine riders, for, in spite of being so handicapped by the majority of their machines, they put up startling performances on the racing track, and the percentage of non-stops in their reliability trials is exceedingly good."

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns—9d. per line of 8 words; minimum, two lines. Name and address must be counted. Thus—

Two lines (16 words or less) costs 1/6
Three lines (24 words or less) costs 2/3
Four lines (32 words or less) costs 3/-

In the case of Trade Advertisements a series of thirteen insertions is charged as twelve.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor Street, E.C.), on Tuesday morning previous to the date of issue.

When possible advertisements received at Coventry on the Wednesday will be inserted.

All letters relating to advertisement should state distinctly under what heading and in what issue the announcement appeared.

CLASSIFICATION BY LOCALITY

For the convenience of purchasers of second-hand motor cycles, the advertisements are classified into districts, as many readers like to know what machines are for sale in their immediate neighbourhood before going further afield.

Plan showing division of England into Sections.

SECTION I.
Northumberland, Cumberland, Durham, and Westmoreland.

SECTION II.
York and Lancashire.

SECTION III.
Carnarvon, Denbigh, Flint, Cheshire, Derby, Stafford, Shropshire, Montgomery, and Merioneth.

SECTION IV.
Nottingham, Lincoln, Leicester, Rutland, Northampton, Warwick.

SECTION V.
Norfolk, Suffolk, Cambridge, Huntingdon, and Bedford.

SECTION VI.
Worcester, Hereford, Radnor, Brecknock, Monmouth, Glamorgan, Carmarthen, Cardigan, and Pembroke.

SECTION VII.
Gloucester, Oxford, Buckingham, Berks, Wilts and Hants Channel Islands.

SECTION VIII.
Hertford, Essex, Middlesex, Surrey, Kent, and Sussex.

SECTION IX.
Somerset, Devon, Dorset, and Cornwall.

SECTION X.
Scotland.

SECTION XI.
Ireland and Isle of Man.

No. 1926. 3½ h.p. VINDEC SPECIAL, magneto, Truffault forks; Peugeot engine; guaranteed .. £25 0
No. 1924. 8 h.p. J.A.P., M.O.V. low No. 6 Chater-Lea frame, 1909 model, Palmer Cord tyres, drip feed, and force pump lubrication; fast as new, too powerful for solo; guaranteed.. £38 0
No. 1922. 4½ h.p. TWIN MINERVA, powerful M.O.V. engine; guaranteed. First cheque.... £15 0
No. 1923. MONTGOMERY SIDECAR, cane seat, flexible; as new..... £6 10
No. 1921. MILLFORD CASTOR WHEEL SIDECAR, wicker seat; nice condition; complete with apron, guaranteed..... £6 10
No. 1920. 4 h.p. N.S.U., 1909 model, spring forks, and magneto; complete with Castor Wheel Sidecar (or can be sold separate); guaranteed..... £32 10
No. 1917. 3½ h.p. 1909 TRIUMPH, Palmer Cord tyres, condition like new; guaran. Lowest price £35 0
Two 1½ h.p. MOTOSACOCHES, low frame models, magneto ignition, late 1909 machines, condition as new; guaranteed ..... each £23 10
Three 1½ h.p. Lightweight F.N., complete with magneto and spring forks; up to date; all guaranteed ..... from £15 0
Eight 1909 3½ h.p. Standard REX Tourist models, brand new, complete with stand, carrier, tools, no plates; ready for the road; usual price £42. To clear ..... each £35 0
No. 1887. 3½ h.p. QUADRANT, magneto, spring forks, Birmingham make, smart, and good sound roadster; guaranteed £17 10
2¾ h.p. 1909 DOUGLAS, new last May, in excellent condition; guaranteed. Lowest price £25 0
Six 1½ h.p. MOTOSACOCHE Lightweight Motor Cycles; all guaranteed ..... from £12 10
Two 3½ h.p. HUMBERS, two speeds, 1909 models, magnetos, and spring forks ..... from, each £28 10
No. 1898. 3½ h.p. 1908 TRIUMPH, condition better than new, guaranteed at Wauchope's.. £32 0
No. 1894 & 1895. 9 h.p. BAT, and sidecar..... Offers
No. 1896. 9 h.p. RILEY Tricar, nice condition, side doors, three speeds & reverse, guaranteed £35 0
No. 1881. 3½ h.p. QUADRANT, magneto, low frame, splendid machine, guaranteed..... 19 Gns.
No. 1853. 4½ h.p. HUMBER Tricar, water-cooled, coach-built front seat, first cash..... 10 Gns.
No. 1874. 1½ h.p. MOTOSACOCHE, 1907 model, in nice condition; guaranteed £15 15
No. 1873. 2 h.p. 1908 MOTO-REVE, grey finish, smart machine; guaranteed ..... 21 Gns.
No. 1867. 3½ h.p. ARNO, two-speed gear and free-engine clutch, up-to-date machine, in new condition; guaranteed £32 10
No. 1861. 3½ h.p. BAT, sound machine, fit for the road; guaranteed £12 10
No. 1855. 1½ h.p. MOTOSACOCHE, perfect order, ready for the road; guaranteed ..... 15 Gns
No. 1847. 2 h.p. 1908 MOTO-REVE, twin-cylinder engine, spring forks, magneto ignition, splendid condition, direct V belt drive; guaranteed .. 19 Gns.
No. 1845. 3½ h.p. brand new PHELON & MOORE. 1909 model, two-speed gear and free engine. Offers.
No. 1842. 3 h.p. TRIUMPH, spring forks, 1906 model, nice condition throughout; guaranteed £16 10
No. 1837. 3½ h.p. 1907 MINERVA, smart machine; guaranteed £13 10
No. 1836. 2¾ h.p. MINERVA, 1907 machine, nice condition; guaranteed £12 10
No. 1835. 1¾ h.p. MOTOSACOCHE, mag. ignition, '09 model, spring forks, as new; guaranteed .. £23 10
No. 1834. 3½ h.p. TRIUMPH, 1909 model, magnificent machine; guaranteed £35 0
No. 1829. 3 h.p. SCOTT-JOWETT Two-stroke £25 0
No. 1828. 3½ h.p. 1909 TRIUMPH, all accessories, magnificent machine; guaranteed £35 0
No. 1826. Sidecar, rigid type, second-hand £4 4
No. 1814. 3½ h.p. MATCHLESS, magneto in tank, Druid spring forks, nice machine; guaranteed 20 Gns.
No. 1813. 3½ h.p. FAFNIR, nice condition, accumulator ignition, sound machine; guaranteed 9 Gns.
No. 1810. 3½ h.p. PEUGEOT in No. 6 Chater-Lea frame, low frame, torpedo copper tank, good, sound machine; guaranteed ..... 17 Gns.
No. 1801. 2½ h.p. 1908 Featherweight REX, nice condition, magneto ignition; guaranteed £17 0
No. 1764. 5-6 h.p. Four-cylinder F.N., 1908 model, good, sound condition; guaranteed. Price .. £25 0

Second-hand and New Bargains quoted in this column are offered for sale by WAUCHOPE'S. Dozens of bargains besides those quoted can be inspected on the premises at 9, SHOE LANE. Inspection is cordially invited.

WAUCHOPE'S,
9, Shoe Lane, Fleet Street
(off Ludgate Circus),
LONDON, E.C.

Telephone, 5777 Holborn. Telegrams, "Opificer, London."

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, 2d. will be charged for registration and three stamped and addressed envelopes must be sent for forwarding replies. Only the number will appear in the advertisement. Replies should be addressed, "No. 0000, c/o 'The Motor Cycle,' Coventry"; or if "London" is added to the address, then to the number given, c/o "The Motor Cycle," 20, Tudor Street, E.C.

DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt, and upon intimation of the arrival and acceptance of the goods, the money is forwarded less a charge of 1s. for registration. The time allowed for a decision after receipt of the goods is three days, and if no sale is effected, each party to the transaction pays carriage one way. For transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe and Sons Limited.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

MOTOR BICYCLES FOR SALE.

SECTION I.

Northumberland, Cumberland, Durham, and Westmoreland.

F.N. 4h.p. 4-cyl. Motor Cycle, with the latest type of frame, footrests, and many additions and spares; first offer of £26, very cheap.—Rae, Thoroton St., West Hartlepool.

SECTION II.

York and Lancashire.

1910 Ariel, Douglas, Bradbury, Norton, F.N., Indian, Premier, N.S.U.—Gourlay, Fallowfield.

F.N., 2h.p., first-class condition, new back tyre, spares, £5 10s.—Lister, Burnedge, Whitworth, Rochdale.

WERNER 2¾h.p. Twin Lightweight, spring forks, good order; trial; bargain, £10.—Stanley Park, Roebuck Hotel, Bolton.

BRAND New 1909 Triumph, Dunlops, complete; £—Cross, Triumph agent, Rotherham.

1909 Brown, 3½h.p., Druid forks, B. and B., handle-bar control, fine order; £29.—Cross, Triumph agent, Rotherham.

1909 Triumph, R.O.M. tyres, fine order, headlight, horn, tools, numbers; £36. — Cross, Triumph agent, Rotherham.

3½h.p. Minerva, spring forks and seat, handle-bar control; £12.—Houghton, fishmonger, Rotherham.

3½h.p. Spring Bat, good condition; reason for selling £8.—Newsagent, 224a, Kensington St., Girlington, Bradford.

3½h.p. Brown, £10; 3½h.p. Fafnir, £10; 3½h.p. Humber, with forecar attachment, £12.—20, Potternewton Lane, Leeds.

1909 Special Show Model 5h.p. Twin Rex, condition and appearance like new; bargain, £35.—Particulars given on application, Hartley, 47, Walnut St., Southport.

LIVERPOOL Motorists should, to protect their interests, buy Triumph, Douglas, Scott, and F.N. motors only from the responsible official agents, Hitchings, Ltd., 74, Bold St., who alone can substantiate the makers' guarantees, and also supply spare parts from stock.

TRIUMPHS.—Hitchings, Ltd. (the official agents), have several second-hand machines for sale at low prices, 1907, 1908, and 1909 models; all guaranteed; inspection invited.—Hitchings, Ltd., 74, Bold St., Liverpool.

SCOTT 2-stroke 2-speed Water-cooled Motor Cycles (of which Hitchings, Ltd., are the sole Liverpool district agents) should be ordered now to ensure early delivery; send for descriptive catalogue.—Hitchings, Ltd., 74, Bold St., Liverpool.

LIGHTWEIGHT Douglas and F.N. motors, latest models in stock at 74, Bold St., Liverpool.—Hitchings, Ltd., are the sole agents, and invite enquiries.

MINERVA and Rex.—We carry the largest stock of spare parts in the provinces for these machines, can deliver new machines from stock at low prices, cash, exchange or gradual payments; charged accumulators for hire, 1s. per week. — Cookson Bros., 5, Chester Rd., Old Trafford.

In answering these advertisements it is desirable to mention "The Motor Cycle."

THE MOTOR CYCLE SUPPLEMENT

ROTARY VALVE ENGINES.

"THE use of the rotary valve for internal combustion engines is far older than seems to be supposed, and, considering that the existing conditions are much the same as they were some years ago, when these valves were not successful, it will be matter for surprise if they should succeed now. A combined rotary inlet and exhaust valve operating between twin-cylinders was used by a firm in Cleveland, Ohio, as far back as 1902, but was abandoned by reason of its rapid deterioration through wear.

"The valve and seating were both ground by an expensive Brown and Sharpe grinder, and made as perfect as could be. The valve also ran in an oil bath. Despite these precautions it soon became leaky. The old Dawson rotary piston engine was about the best. It was at once a rotary valve and piston sleeve, and, so far as this function is concerned, was satisfactory."

So writes our valued contributor "Incandescent," but we think that he is unaware of, or has forgotten, the Butler rotary valve, which was the invention of Mr. Edward Butler, one of the pioneers of the British motor industry, who exhibited a motor tricycle at the Inventories Exhibition in 1884, which was known as the Butler petrol cycle. Later he invented the conical rotary valve, and this was fitted to a large number of Clark-Chapman gas engines, and it is still in regular use on these engines. Mr. Butler also applied the rotary valve to the engine of a Bollée tricycle as early as 1899, so that it will be seen he long ante-dated the American inventors. These Butler rotary valves have been quite satisfactory, but the objection to them from the motorist's point of view is that they must always be lifted from their seats when stopping; otherwise the unequal expansion of the metals of which the valves and their seatings are made results in binding and even seizure of the two surfaces. On the other hand we do not know that the Butler rotary valve has been found to possess any special advantages over the poppet type. It undoubtedly had advantages of its own for the purpose for which it was originally introduced, as each valve could be arranged to serve two cylinders. From the motor cyclist's point of view the great attraction of the Butler conical rotary valve would be the fact that it would never require grinding, as it performs that operation automatically in the course of its ordinary working. A similar rotary valve to the Butler was described and illustrated in *The Motor Cycle* of April 7th, 1909. This was patented by Mr. A. H. Williams, Chester, and a contributor's experiences with it were published in the same year on page 322, May 15th. The rotary valve on this engine had to be copiously oiled, and the cylinder was provided with an auxiliary exhaust release.

A.C.U. AND AFFILIATED CLUBS.

On December 31st last forty-eight motor cycle clubs were affiliated to the Auto Cycle Union, the number of riders represented, including the membership of the A.C.U., being 2,674. The corresponding figures of 1908 were thirty-six organisations representing a membership of 2,253. It will thus be seen that in twelve months twelve new clubs, with a total of 421 members, have thrown in their lot with the A.C.U.

MOTOR CYCLING CLUB.

Below will be found the fixture list for 1910. Encouraged by the large number of entries for the races and gymkhana events at Brooklands in the late autumn, the M.C.C. has engaged the Brooklands track for Saturday, June 4th, 1910. It is proposed to run a sporting club programme on similar lines to the last series, namely, races for cycles and cars, and gymkhana events. It is also hoped to include an invitation match for crack top speed merchants.

Mar. 12th.—Opening run to Brighton.
At Easter. Easter tour. Jarrott cup competition.
Apr. 30th.—Members' hill-climb.
May 13th, 14th, 16th.—London-Edinburgh and London-Edinburgh and back runs.
,, 28th.—Car competition for Albert Brown trophy.
June 4th.—Race meeting and gymkhana at Brooklands for cars and motor cycles.
,, 18th.—Inter-team trials for *The Motor Cycle* cup.
,, 25th.—Petrol consumption trial.
July 23rd.—Twelve hours' trial.
Sept. 10th.—Members' hill-climb.
,, 28th.—Brooklands A.R.C. Easter Meeting.

FUTURE EVENTS.

Jan. 6th.—Essex M.C. Paper on "Magnetos," by Mr. A. Bennett, Great Eastern Hotel, Liverpool Street, E.C.
,, 7th.—Western District M.C. Annual General Meeting.
,, 13th.—A.C.U. "The Problem of the Private Owner." A paper to be read by Mr. P. W. Bischoff.
,, 15th.—Essex M.C. Annual Dinner.
,, 20th.—A.C.U. annual dinner. Waldorf Hotel, H.S.H. Prince Francis of Teck, G.C.V.O., D.S.O., presiding.
,, 29th.—A.C.U. Quarterly Trial, Uxbridge to Banbury and Back.
,, 29th.—Birmingham M.C.C. Annual Dinner.
,, 29th to Feb. 5th.—Scottish Cycle and Motor Cycle Show, Promenade Hall, Edinburgh Marine Gardens.
Feb. 3rd.—Royal A.C. and Associated Clubs' Second Annual Dinner.
Mar. 12th.—M.C.C. Opening Run.
,, 25th.—General Meeting of Northern Motor Cycle Clubs at Richmond, Yorks.

Current Chat

The New Year.

A happy and prosperous New Year to all our readers!

The Editor wishes to thank numerous readers who have sent Christmas and New Year greeting cards.

Eighth Year of "The Motor Cycle."

This issue commences a new volume—No. 8—of *The Motor Cycle*.

Lamp Lighting Times.

The times to light lamps for this week are:

Jan.	3rd	5.1	p.m.
,,	5th	5.3	p.m.
,,	7th	5.6	p.m.
,,	10th	5.10	p.m.

America Claims World's Speed Record.

Mr. E. L. Ovington (formerly president of the F.A.M., and at present a member of the F.A.M. Competitions Committee), who is now in this country, claims for Fred Huyck (one of the most successful American riders) the fastest speed ever accomplished on a motor bicycle. When he made his marvellous record of a full mile in 42⅗s., *i.e.*, 84½ miles per hour, on a 7 h.p. Indian, on a three-lap track, Huyck covered the second lap in 13⅕s., equal to a speed of 90.91 miles an hour. These figures have been specially pointed out to us to prove that it is not necessary to have a "freak monster" in order to capture world's records for a motor bicycle. The same remarks apply to racing motor cars; the vehicle with the biggest engine is not necessarily the fastest.

A New Convert.

Mr. J. D. Rockefeller, jun., son of the multi-millionaire, has been won over by the motor bicycle. He was seen recently riding through Tarrytown, N.Y., attired in a khaki suit, with a sweater under his coat. He was not exceeding the speed limit!

Motor Cycle Repairers.

The A.C.U. Touring Department is now appointing motor cycle repairers throughout the country. The first to be appointed was that well-known racing man, Dudley R. Clarke, of the New Century Motor Co., St. Albans. Complaints having been received as to the want of attention on the part of some general repairers when dealing with motor cyclists, a letter has been sent to the firms in question warning them that, unless the same attention is given to a motor cyclist as to a car owner, the appointment will be withdrawn.

Two Clubs Amalgamate.

The St. Albans and District M.C.C. is now formally amalgamated with the Hertfordshire County A.C., and the result is a very strong motor cycle section of the latter body. Some open competitions are on the *tapis* for 1910.

The ubiquitous motor cycle in Nyassaland. At one time the natives scampered for the nearest place of retreat at the sound of a motor cycle, but judging by their intent gaze on the Fairy motor bicycle in the illustration, they have now mastered their former fears. Incidentally, the machine (which is owned by Mr. Norman, of Blantyre, Nyassaland) has been running since 1908 quite satisfactorily, although the roads are by no means of the best.

Licences for Motor Cycles.

It is not generally known that [illegible] for motor vehicles need not nec[illegible] be taken out in the county in wh[illegible] owner resides. Consequently it [illegible] legitimate and perfectly rea[illegible] course for automobilists and motor[illegible] who have been subjected to unne[illegible] persecution and expense, not [illegible] the payment of fines which a fair-minded bench would never inflict, but also in the wear of tyres on roads purposely neglected for the object of keeping motorists away, to take out their licences in unprejudiced counties. Some county councils, recognising that a good deal of their revenue may possibly be lost by motorists taking out their licences in different counties, issued notices last week, marked "Important," urging licencees to take out their licences at post offices within their respective counties, and pointing out that the produce of these licences is handed over to county councils for the benefit of the county rates. Readers in Warwickshire, Su[illegible] Buckinghamshire have sent us the notices they have receive[illegible] can Warwickshire, Bucks, an[illegible] fairly ask for the licences to [illegible] out in their counties when sev[illegible] of direct persecution have co[illegible] the notice of our readers? [illegible] words, they now ask for con[illegible] when they have given motoris[illegible] sideration at all—that is, of [illegible] sort! For that reason, we [illegible] motor cyclists who reside i[illegible] counties to be guided by [illegible] knowledge and feelings in taki[illegible] 15s. licence. It is certain [illegible] numerous motor cyclists who,

M. [illegible] numer[illegible] mount[illegible] Indian. [illegible] are ca[illegible]

A.C.U. Annual Dinner.

Those members and affiliated members of the Auto Cycle Union who intend to be present at the annual dinner at the Waldorf Hotel on Thursday, January 20th, should notify the secretary immediately. An excellent musical programme is to be given during the evening, and the speeches will be few, but doubtless interesting, as usual. The A.C.U. president, Prince Francis of Teck, G.C.V.O., D.S.O., will be in the chair.

On the Warpath.

No less than six ans have been entered for the Inter- onal Tourist Trophy Race. As has reported, two entries have been ved from W. H. Wells, with, in tion, three from the Hendee Mfg. who are sending over American rs (probably F. Huyck, Derosier, and Goerke), and one from W. O. Bentley. virtue of his win in the last race, A. Collier is entitled to start first he T.T. Race this year.

Jarrott Cup Competition.

iis year the M.C.C. long-distance for the Jarrott Cup will be held at er, and it is expected that more ies will result.

The Friendly Match.

In *The Motor Cycle* last week, Mr. F. H. Mullett offered to ride his Triumph against Mr. H. C. Tromp van Diggelen's Wanderer at Brooklands or the Stadium for any distance Mr. Diggelen liked to name, the challenge being the outcome of the latter's contention that in the last race he had not sufficient distance in which to attain his best speed. After going to press with our correspondence pages, we received the following letter: "I have read Mr. Mullett's letter in the last issue of *The Motor Cycle*. To settle all paper arguments I will agree to meet Mr. Mullett as well as any other private rider of a 3½ h.p. standard touring machine on the Brooklands track, the distance to be not less than fifty miles, with a standing start. The race to take place during March or April. (Signed) H. C. Tromp van Diggelen."

Will the Wanderer Win?

Writing from Odessa, Mr. A. H. King (who owns two motor cycles) says: "I see Mr. Tromp Van Diggelen lost his race, but I believe he will still make the challenge good. Certainly a Wanderer can show a clean pair of heels to anything here."

New Speed Limits.

The following ten-mile limits recently came into force: Sawbridgeworth, Herts, main London to Cambridge road, from Hoestock Lane to a point ten yards north of the junction with Barker's Lane; East Grinstead, Sussex, main London to Lewes road, from the middle of the bridge over the Tunbridge Wells and Three Bridges Railway to a point twenty yards east of the junction with College Lane.

Alteration of Date of Stanley Show.

Since we announced the date of the 1910 Stanley Show, the directors, after careful consideration, have decided to advance the dates slightly. November 11th to 19th, both dates inclusive, have now been decided upon, the change being consequent upon the proposed alteration in the date of the Olympia Motor Show, it having been the practice of the Stanley Show to arrange a date so that country and foreign visitors could attend both shows at one visit.

Ball Bearing Crankshafts.

Respecting the influence of the design of motor bicycles on motor car construction, Mr. S. F. Edge writes to *The Autocar* that there is one point in comparing the use of ball bearings on the crankshaft of motor bicycles and motor cars which has not been dealt with, and that is the reason why he considers that the ball bearing crankshaft has not been very successful with motor cars, viz., the fact that it has a tendency to make a noisy engine.

"THE MOTOR CYCLE" IN THE SOUTH AUSTRALIAN BUSH.

Leonard Bentley (brother of the three enthusiastic amateur motorcyclists, A. W., H. M., and W. O.) He has written on the back of the photograph: "*The Motor Cycle* is a boundary rider's comfort back in the N.E. or never never country, South Australia."

CLUB NEWS.

Middlesbrough and District M.C.C.

On the 12th inst., at the Corporation Hotel, Middlesbrough, Mr. J. Bellerby will read a paper entitled "Benzol—Its Constitution and Best Methods of Using." Members are invited to take their friends to the lecture, which commences at 7.45 p.m.

Sutton Coldfield A.C.

The annual dinner of the above club will take place on Saturday next, the 8th inst., when it is hoped that a goodly number of members and friends will attend. The Mayor (Councillor T. H. Cartwright) has kindly promised to preside, and the Mayoress has graciously consented to present the prizes won during the past season. Messrs. J. W. Orde and H. Gillard Cove have also promised to attend.

As arrangements will shortly be made for calling the general meeting of the club, the hon. secretary, Mr. H. R. Lane, will be glad to hear from motorists (both car and cycle owners) in the district who are desirous of joining. His address is The Beeches, Anchorage Road, Sutton Coldfield.

Western District M.C. (London).

The committee sincerely hope that every member of the club will endeavour to be present at the annual general meeting, to be held at the Milford Hotel, London Road, Spring Grove, Isleworth, on Friday next, the 7th inst., at 8 p.m.

There are several important questions to decide, and it is very desirable that all the members should meet together in order to voice their views on matters relating to the club, and take part in the election of officers and committee for the ensuing year.

Copies of the agenda may be obtained from the hon. secretary, Mr. F. H. Mullett, 53, Kingsley Avenue, West Ealing, W.

Sunderland and District M.C.C.

A well attended smoking concert was held at the Grand Hotel, Sunderland, Major Vaux, D.S.O., presiding, when the successful competitors in the various competitions were awarded the prizes as follows: Speed-judging competition, held on May 12th, distance 12 miles—E. J. Tiffin. One hundred miles non-stop run for the Vaux Challenge Shield, in June last—F. Turvey, jun., 1; E. J. Tiffin, 2. Reliability run to Wakefield and back, on July 17th, for the Turvey Challenge Shield—J. Jack, 1; E. J. Tiffin, 2; F. Turvey, jun., 3; and Q. Nichol, 4. Speed-judging competition over twenty miles circular course—E. J. Tiffin. 1; F. Turvey, jun., 2. In a run held in conjunction with the North-Eastern Automobile Association and the Newcastle Motor Cycle Club, three first prizes were secured by members of the club, the successful competitors being F. Turvey, J. Jack, and E. J. Tiffin.

Hertfordshire County A.C. (Motor Cycle Section).

Members are asked to please note that the headquarters of the club are the Red Lion Hotel, St. Albans.

A club room comfortably furnished and replete with papers, writing accommodation, etc., for the convenience of members and their friends, will be ready for use in the course of a few weeks. A special tariff has also been arranged with the proprietor of the hotel, particulars of which will appear in the handbook.

The committee elected by the members at the annual general meeting on December 17th is a very representative one, and all are enthusiastic amateur motor cyclists.

The club is now in a very strong position, and the number of prospective new members, who are to be elected at the next committee meeting, promises well for the future success of this organisation.

A novel feature of this year's programme will be a series of inter-county team competitions in various parts of the country.

Readers desiring further information respecting the club should apply to the hon. sec., Mr. C. C. Cooke, North Mimms, Hatfield, Herts.

Bolton and District M.C.C.

The annual general meeting has been fixed for January 19th. Arrangements are being made to have a lantern lecture on "Magnetos" after the annual dinner, which latter event has been fixed for February 2nd.

Edinburgh M.C.C.

The fourth annual dinner will be held at the Carlton Hotel, Edinburgh, on Friday, January 21st, 1910, at 7.30 p.m. The price of the tickets is 4s. Members requiring extra tickets can obtain them from the hon. sec., Mr. G. J. Ewen-Watson, 63, Queen Street, Edinburgh.

Essex M.C.

The second of the series of papers included in the winter programme will be given on Thursday, the 6th inst., when Mr. A. Bennett will give a lecture on the high tension magneto, Lantern views will be used to illustrate the lecture, which will take place at the Great Eastern Hotel, the chair to be taken by Mr. F. J. Jenkins at 8 p.m.

North-west London M.C.C.

The third annual dinner at the Criterion Restaurant, with the president, Mr. W. Pidgeon, in the chair, was an unqualified success, a large number of members and friends (including ladies) being present. Both the chairman and Mr. Williams reviewed the work and progress of the club during the past twelve months, pointing to the satisfactory growth of membership and increase in the entries received for the various competitions. Mr. Straight represented the Auto Cycle Union, and Messrs. Brighton. Rowden, and Middleton also spoke. Miss Muriel Hind gave away the numerous prizes with as much ease and charm as if she were doing fastest time in a hill-climb.

The members received a grievous shock when Mr. A. Stanley Phillips announced his intention of resigning the captaincy, owing to pressure of business. Mr. Phillips has been captain since the inception of the club, and its success is in a great measure due to his untiring energy.

An Address Wanted.

Can any reader furnish us with the address of the makers of the Givandan engines, or an address where spare parts can be obtained?

The Tourist Trophy Race.

Entries for the T.T. Race now total eleven, the latest entries to be received being one from C. B. Franklin, and three from the Triumph Cycle Co., Ltd.

The New T.T. Capacity Limit.

The decision of the A.C.U. to limit twin-cylinder engines in its competitions to 670 c.c. has led to the Rex Motor Manufacturing Co., Ltd., issuing a notice to the effect that motor cyclists requiring engines of 670 c.c. capacity instead of the standard Rex type (which is 750 c.c.) can be supplied with same without extra charge.

Motor Cyclist v. Roller Skater.

An interesting race was arranged to take place on Saturday evening at the Dragoon Roller Skating Rink, Harrogate, between H. D. Anslow on roller skates and Fred Mackay on a 2¾ h.p. Rex motor bicycle. Mr. Mackay is one of the most consistent riders of a motor cycle in the North. It was not anticipated that high speeds would be attained as the rink is only eighteen laps to the mile.

A Warning.

Readers are warned against sending cash, post-dated cheques or money orders to advertisers of well-known machines when such machines are offered at ridiculously low prices somewhere in the neighbourhood of less than half their market value. We have had proof within the last week or two that several readers have been victimised in this manner, and we would again urge the necessity of adopting our deposit system, which was purposely inaugurated to prevent fraudulent dealing.

The Show Question.

WHATEVER the decision of the bulk of the motor cycle industry with regard to the show question, the rider and purchaser of motor cycles is chiefly interested in how the machines he rides will be displayed and where they will be housed. In trade circles the question of the hour is, Will there be two shows for cycles and motor cycles this year or only one? The amateur motor cyclist, to whom this journal particularly appeals, is not interested in trade discussions as to how long this or that exhibition has existed and which ought to have the support of the industry, but he wants to know where the exhibition is to be held, and more particularly he desires to impress on all concerned that he wishes a voice in the method of organising the show. The rider and buyer is, in our opinion, not sufficiently considered in these matters. He cannot, of course, expect to be directly represented on a committee of management having the organisation of the exhibition under its control; but his grievances should be listened to, and if he desires a certain arrangement of the exhibits, or a change in the situation or date of the show, he should not be ignored. After all, who enables the show to be held? Is it the agent and dealer who goes to the show to talk about next year's trade and to see what changes have been made in design, and perhaps to place an order, or is it the rider? Doubtless the answer is "both," but without the rider there would be no necessity for the dealer and agent; and if the management of a show was assured from the commencement that riders would not attend, it is improbable that the show would be held for the trade alone. For that reason the rider should receive rather more consideration than he does at present. One of the first things is to separate pedal cycle and motor cycle exhibits; this action would be appreciated by both pedal and motor cyclists. The next is to advertise the motor cycle side of the show more, and give motor cyclists a better chance of knowing that the show, wherever it is held and whoever are the promoters, is essentially a motor cycle exhibition, and not a pedal cycle show with motor cycles as a side-line. The date of the exhibition should also receive the most careful attention of all concerned. At present the date is one selected as the most convenient for the manufacturer. The busy season is over and new designs are practically settled; he can therefore show the new models, and any point which receives adverse criticism can be altered before the time of heavy and urgent deliveries is upon him. It is very questionable, however, if the date is a good one for private purchasers, and a show a little later would probably suit the trade as well, and result in far more business being done with the actual riders of the machines and users of the various accessories. At present the Stanley Show and the Cycle and Motor Trades Association may both hold a show in 1910, but the projected combined show of motor cycles and pedal cycles, which the Cycle and Motor Trades Association wished the Society of Motor Manufacturers and Traders to hold at Olympia, will not take place, because at the general meeting of members of the latter body, a sufficient majority was not in favour of altering the articles of association to render it possible.

ACROSS THE BORDER.

By ALLAN PHILLIP.

THERE may be many English motor cyclists who would gladly ride across the Cheviots and explore the land of the Scots, but who are deterred from so doing either by the thought of the mountainous nature of the country, or the time required to reach the Border from the Metropolis. The latter is often a deterrent, particularly when the vacation happens to be a short one. Anyone, however, wishing to make acquaintance with some of the finest scenery in Great Britain may be interested in the following description of a short tour undertaken on a low-powered tricar. The route followed is easily within the abilities of any low-powered machine, be it bicycle, tricar, or sidecar. Over the whole distance an old-pattern 3½ h.p. Rex with detachable forecarriage carried my wife and myself, and I cannot remember one hill on which it was necessary for my passenger to dismount.

The Border Bridge, Berwick-on-Tweed.

We crossed the Border separating England from Scotland at the historical town of Berwick-on-Tweed, by the old stone bridge, from which is obtained such a fine view both seaward and landward; then made our way through two or three narrow streets and up the long hill that runs through the heart of Berwick, and so on under the span of its ancient walls.

As soon as the town is left behind it is well to leave the motor and walk across the fields on the left-hand side of the road as far as the edge of the bluff. From this vantage point a fine view is obtained of the Border Bridge, with its twenty-eight arches spanning the famous Tweed.

Sir Walter Scott's School.

From Berwick to Kelso the road is good, and in five miles we touch land made sacred by the memory of Sir Walter Scott; in a house adjoining Kelso Abbey the famous poet and novelist passed his schooldays.

Dusk was giving place to darkness when we filled up the tank with petrol at Kelso and rode onwards for Melrose. Owing to the darkness we only saw the scenery bordering this road by the aid of the light of our lamps, and after torrential rain, but I imagine it must be delightfully pretty. At this point our enjoyment was somewhat marred by the slipping of the belt owing to the wet; it was a leather belt, and a little earth from the roadside rubbed on to the sides helped it to grip, but, I fear, did not improve the surface of the pulley groove.

By the aid of illegible signposts, the meaning of whose names we vainly strove to decipher in the light of a detached lamp, we pressed on, or rather groped our way, towards St. Boswells. Dropping into the valley, we ploughed our way through flooded roads and under dripping trees towards the far-off lights of Melrose.

It was 11.30 p.m. when we rode into the town; all was silent, deserted, and dark, and the music of the exhaust echoed and re-echoed among the walls and houses. We pulled up in the Market Square, but there was not a sound or sign of life, and, although we had previously engaged rooms, we had no idea where to find them. Then out of the darkness there emerged the solitary figure of a man, who proved to be our salvation and the provider of all our needs. His was the shed wherein we stowed our steed, his were the steps that guided us to our abode, and his the hand that bore the burden of our luggage; and —were he not a Scot I might say "wonderful to relate" —he would take nothing for his pains!

Our hostess, giving up all hope of seeing us that night—it was now well past midnight—had extinguished the light in her house and retired for the night. All was dark and silent. Repeated knocks at length had their desired effect, and the door was opened. Were we met with muttered oaths? No! but with a Scotch welcome—kindly and unfeigned. She made us hot coffee, and rested not till we were comfortable for the night. May it be that our first two acquaintances across the Border will be such as my readers will ever find when they seek the hospitality of Melrose.

Across the Border.—

Much time may be spent at Melrose. There is its abbey to be inspected, the Eildon Hills to be climbed, and Dryburgh Abbey, nigh at hand, should certainly not be missed, while Abbotsford stands imperatively upon the programme.

The Forth Bridge, looking south.

I do not know a finer section of road in the kingdom than than between Melrose and Galashiels. The latter town is scarcely touched, and the road bends north toward Edinburgh.

At Galashiels a tappet broke, and we spent an hour in the hot sunlight replacing it by a spare one, a damaged tappet which had been discarded once; but it carried us many miles, and I still carry it as an emergency stand-by.

Our road now ran through charming scenery. The River Gala was on our left, and the road was shaded by trees for mile after mile. Delightful quarries, silent and deserted among the trees, make ideal spots for a wayside lunch.

We now commenced the long, gradual rise up to Heriot; but at no part is the gradient severe. Through Stow, with its pretty bridges, we passed, and thence onward to the bleaker country on the hill tops. From Heriot a long and mostly downhill run took us into the crowded streets of Edinburgh, thence on to Queensferry and the shore of the Firth of Forth. We were ferried across the Forth by steamer, and from its decks obtained a splendid view of the Titantic Forth Bridge, that mighty engineering feat which everyone who visits Edinburgh goes to see if he can reasonably spare the time. In fact, it is one of the sights of Edinburgh; although not in the city, it is in very close proximity to it.

Having landed and climbed the hill beyond the Forth, at a bend in the road we had a fine backward view of the bridge, stretching like a mighty centipede across the waters of the Forth.

For the next hour or so the journey was over the least interesting portion of the whole route, Loch Leven on our right alone calling for attention.

The monotony of the ride to Kinross was broken for us by the only accident we have ever had. We were mounting a fairly steep hill at a smart pace when we met a large herd of cows descending. They divided into two columns, and left the whole road clear; but somehow as we neared the middle of the herd they closed in suddenly and unexpectedly from the left, and charged directly across our path. We missed the first cow, just grazed the second somewhat severely, and charged the third broadside on with considerable force. The whole affair occupied so short a time that I had scarcely thought to apply the brakes before we came to an involuntary stop.

My wife disentangled herself from the cow, which rejoined its companions, and, luckily for us, we escaped without personal damage. The poor tricar, however, suffered a broken bolt and a much-distorted frame. The bolt was replaced at Kinross, but the distortion cost me two new outer covers before we reached home, owing to faulty alignment of the front wheels.

Beyond Kinross we again entered lonely country, and the ride through Glen Farg will always be a memorable one for us. Perth was bathed in the light of a golden sunset as we entered through its "Inches," and early morning saw us again on our way, this time *en route* for Dunkeld and Burnham, and thus to Aberfeldy.

Aberfeldy lies in the very centre of a paradise of excursions. We had time for none, but a day or two might very enjoyably be spent in the locality, and the Falls are worthy of a visit if all else be missed.

By the time we reached Loch Tay rain was falling heavily, and a strong head wind was blowing. A gale from the west was sweeping over the loch, raising waves which rolled wildly towards the shore and broke in spray on the stony beach. Over rough and swamped roads we reached Lawers' Hotel, but did not stay. It was a drenching ride and hard, for the shrieking wind beat the blinding rain unmercifully in our faces, and it was dusk when we reached Killin. Even in that driving mist and cold wind we could not fail to

Holyrood Palace, Edinburgh.

Across the Border.—

admire the beauty of the loch, dark under those heavy storm clouds, and the frowning mountain partly hidden in the mist.

Hemmed in by Beauty Spots.

Killin itself is simply hemmed in by beauty spots—the Glen of Lochay, the Forest of Mamlorn, and the

In Glen Farg.

Misty Glen among others. In fine weather Killin would make a tourist centre hard to beat, and the accommodation is excellent.

The following morning in falling rain we passed over the pretty River Dochart, and along the very passable mountain road, through exquisite scenery of mountain, lake, foaming river and sombre pine, to Crianlarich. In sunlight, the whole of this route must be a paradise of loveliness.

At Crianlarich the rain ceased and the hot sun streamed through the steaming air. We threw off our mackintoshes, and, delighting in the freedom, regaled ourselves with a wayside meal, with the inimitable vista of hill and vale and receding storm cloud spreading out before us.

In spite of rain and heavy roads, our little Rex

Bridge at Aberfeldy.

ran magnificently all the way, causing no anxiety and little thought. It was at this spot that we turned south towards Loch Lomond. The country here is very black. One feels the weirdness of mountain loneliness and moorland solitude, but there is a glorious inspiration in the very desolation of the place.

The River Falloch runs beside the road, murmuring over the stones or roaring like distant thunder as it pours heavily over a shelving ledge into the deep pool beneath. Lovers of the beautiful will do well to dismount once or twice and cross the grass to the water's edge to appreciate the charming bits of scenery all along the river's course.

A Tempting Section of Road.

The run from Crianlarich to Ardlui is downhill, and so easy going that one is tempted to hasten. It seems a shame to check speed on such a gloriously easy road, but either exhilaration of speed or enjoyment of the beauties of nature must be sacrificed. It is a matter of personal choice.

Soon the road dips down into the verdure of the trees, and the scenery at the head of Loch Lomond and along Glen Falloch is worthy of full admiration.

But there is better yet to come. At Ardlui we come upon "the shining levels of the lake," and now

Loch Lomond, at Ardlui.

for nearly twenty miles the road wound along the margin, with fern-clad rocks and trees on our right and the silent lake below us on the left.

At Tarbet, halfway along the loch, steamer may be taken across to Inversnaid for the Trossachs, but motors are not allowed on the Trossachs roads. We continued south through Luss, then round the southern end of the lake through Balloch.

Near Luss we experienced an act of kindness which I trust will always be characteristic of motorists. An outer cover of one of the front wheels burst, and while we were seeking to remedy the defect a chauffeur from a neighbouring estate, seeing our difficulty, escorted us into his master's garage, and thoroughly repaired the damage; nor would he accept any payment for his trouble, but sent us forth with best wishes for our journey.

We reached Gartocharn as night closed down over us, and were compelled, very much against our will.

Across the Border.—

to put up at what appeared to be the only hotel. Our previous houses of call were not hotels, and it

Falls of Falloch, near Loch Lomond.

has always been my experience that good accommodation is to be had outside hotels, if you only know where to go.

In the morning we passed through Drymen, and then on to the Stirling Road. This is a magnificent road—long, straight, and level, and, I think, devoid of police traps, or else we were fortunate. The temptation to scorch was irresistible, especially with a strong wind behind!

At Stirling I fitted a new cover, and thence we journeyed through Falkirk and Linlithgow to Edinburgh.

The Homeward Journey.

The journey from Loch Lomond to the Border may be varied in many ways. We followed the route indicated, owing to special circumstances. The distance from Berwick to Edinburgh by this route is about seventy-five miles, and the round from Edinburgh to Crianlarich and back about 200 miles. This route gives one a very fine idea of Scottish scenery—mountain, loch, and forest land, as well as touching some of the most important towns, and most interesting archæological centres beyond the Border.

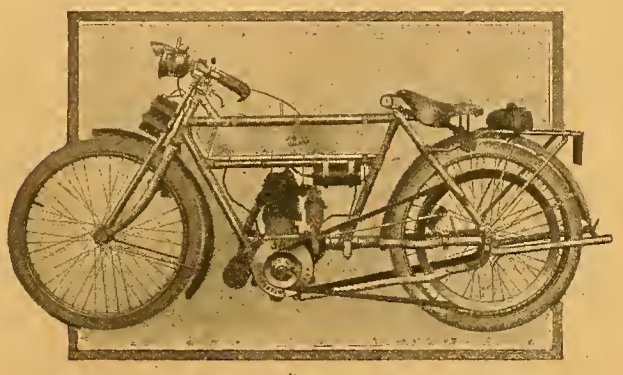
Hotel accommodation is excellent, and we found private apartments comfortable, reasonable, and easy to obtain.

Only once did we fail to find shelter for our tricar, and all one stormy night we left it in a yard, uncovered and open to the road on the wilds of the Lammermuir Hills, near Heriot, guarded by four faithful dogs.

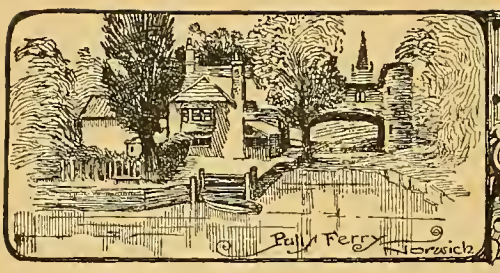
A SIMPLE PROCESS FOR SOLDERING ALUMINIUM.

FOR a long time it was supposed that it was impossible to solder aluminium. Lately, however, one or two methods have been evolved which have been satisfactory, but among amateur repairers we do not know of any which has become popular. A new aluminium solder, however, has been brought out by the Standard Alloys, Ltd., Carpenters Road, Stratford, E., which is quite easy to work. The solder is sold in sticks, and to apply it to the two pieces of aluminium to be soldered it is only necessary first of all to clean the two pieces and to heat them in a blow flame, taking care to let the flame play upon the surfaces to be joined instead of the solder. When the correct temperature has been reached it is necessary to rub the solder on the parts, over which it will flow evenly, tinning them in an effectual manner. When the solder has run properly it should be brushed over once or twice with a metal brush. Each part should be tinned in the same way, and when it is required to join them together it is only necessary to heat them to such a temperature that the solder is melted, and then press the two parts to be joined firmly together, when in a few minutes they will be cool and an exceedingly firm joint will be made. We were shown two pieces of aluminium tube joined together end to end so strongly that a powerful man could not separate them. In most cases it is desirable to use clamps to hold the two surfaces together. Motorists who try this solder should bear in mind that aluminium retains heat, and it is necessary to take precautions to prevent burns which might easily result. Readers will be interested to know that on the occasion of the A.L. solder being demonstrated at these offices one of our staff made a very fair job of soldering two pieces of aluminium together at the first attempt.

The Tourist Trophy model illustrated is a 3½ h.p. Trump-J.A.P., made by the Liphook Motor Engineering Works, of which F. A. McNab, the well-known rider, is the proprietor. The 85 × 85 mm. engine has ball bearings to main shaft and big ends. The carburetter is a J.A.P. automatic, handle-bar controlled, and the ignition by Hellesen dry battery and Hellesen plain coil. The weight of machine as illustrated is 130 lbs., and any of them are said to be capable of 60 m.p.h. on Brooklands when delivered to customers. The machine is finished French grey. Michelin or R.O.M. 26in. × 2in. wired on tyres are supplied to order. The hubs and fittings are Chater-Lea. A standard touring model is built on exactly the same lines, but fitted with bigger tyres, Druid spring forks, Bosch magneto, and ordinary plain bearings to the engine.



A semi-racing model 85×85 mm. Trump-J.A.P. Note the extra stays from rear axle to the base of crank chamber, giving greater rigidity to the engine.



Occasional Comments.

By Ixion.

Rigid Transmissions.

I see Mr. Wharton Metcalfe is appealing for more exactness in wording descriptions of so-called "rigid" transmissions. To be perfectly exact, there are only one or two motor vehicles in the world which can strictly be said to own "rigid" transmissions. There are one or two cars on which the clutch is mechanically locked when a gear is "in," and there are also, I believe, one or two four-cylinder motor cycles on which the transmission forms an absolutely rigid connection between engine and rear wheel all the time. In ordinary practice the term "rigid" is employed to distinguish transmissions possessing one or two points at which slip may take place from other transmissions which allow of slip throughout. Thus for most people a car with cone clutch and gear drive would possess a "rigid" transmission; so would a chain-driven motor cycle with a "spring sprocket" or a "friction sprocket," while all belt-driven motor cycles would rank as "non-rigid."

In the case of motor bicycles the objection to a completely rigid or partially rigid transmission is that if any mishap locks the back wheel or jams the engine a spill is almost bound to result, as for all practical purposes the transmission is "rigid," and cannot yield under the strain. I believe this applies to every existing motor cycle transmission with the sole exception of the belt. A "spring sprocket" becomes rigid when its spring is fully compressed. A friction held sprocket that is tight enough to take the drive up a steep hill will similarly lock up into rigidity if either the engine or the back wheel jams. Against this defect we must, of course, set the compensating advantage of superior weatherproof qualities, at least in the case of the gear drive. It is, however, interesting to read in a recent issue of an American journal that amongst other 1910 tendencies in the States "belt drive is ousting chain drive in most quarters, though many firms still make transmission optional. The V belt will be more popular than ever." American development is obviously profiting by English experience, and I have little doubt that as the Americans learn to make better belts we shall hear less and less of the chain drive in the States. Still, we must not forget that the most popular and best of all the American machines is still driven by chains.

Back-rests for Motor Cyclists.

Some of the younger generation of motor cyclists possibly do not know what the "*fin de siècle*" disease ("motor cyclist's back") is like. We older ones who have done our 300 and 400 miles in a day on the obsolete camel-backed 2¾ h.p. machines know only too well, and so we can understand why inventors continue to place back-rests on the market. If a rider's position is wrong or if he is out of training a run of two or three hundred miles sometimes induces an ache across the small of the back not at all unlike a mild attack of lumbago. Such effects are much rarer nowadays, in this age of low saddles and upswept handle-bars, but some riders are still subject to the pain in the back, shoulders, or neck after exceptionally long runs. When we come to the question of a cure I am strongly in favour of a very low saddle and very high handle-bars. I have ridden 300 miles absolutely untrained on a machine with a very low spring mounted saddle and extremely upswept steering bar grips, and felt no backache at all. If others demand a back-rest, I should advise inventors to make the disappearance of the rest automatic. It is all very well to say that the modern machine is so low that the rider need never dismount by jumping off, but may simply apply the brake and drop his feet on the ground. Occasional emergencies still render a leap out of the saddle essential for safety, and these are just the occasions when a rider may not have the presence of mind to quickly operate some button or lever to release an obstructive back-rest. But every hurried dismount begins with a removal of the rider's weight from the saddle; he either throws it on to the handle-bars, or the footrests, or a pedal. Personally, as an ex-gymnast, I throw it on to the handle-bars. Very well. If a back-rest were so designed that it fell back as soon as the rider's weight quits the saddle there would be no danger or awkwardness about it, and this would be a feature full of attraction to those riders who want back-rests.

Ease of Starting.

I am glad to see that the A.C.U. is awarding a premium for ease of starting in the Quarterly Trials, though five marks are none too many for so desirable a feature. I assert with some confidence that the frequent public spectacle of less capable riders struggling to get their machines started has done more to hamper the progress of the pastime than most things, and I should like to see the A.C.U. apply this principle to the Six Days Trials. If we take our stand in the courtyard of the official hotel on any morning of the Six Days Trials we shall see the riders, almost without exception, injecting petrol or paraffin, pedalling hard, winding away with handles, etc., running their engines on the stand for two or three minutes before entering the roadway and making their official start. Even then a percentage fail to get away cleanly and promptly. We can pardon a machine for being difficult to start on Brooklands, what with a high compression and an enormous gear ratio, and it is, perhaps, excusable in extremely cold weather; but a machine entered as a tourist mount in a road trial ought to start from cold at any rate without preliminary warming up. I think more attention should be paid to this matter of easy starting in the 1910 Six Days Trials.

MACHINES FOR THE COLONIES.

By "IXION."

SEVERAL years of motor cycling journalism have provided me with a very lengthy roll of colonial correspondents, and their comments on the progress of the sport and industry at home are always interesting, and often sulphurous. I am able to estimate from previous letters what many colonial riders will be thinking of our 1910 machines, and it may interest prospective emigrants to hear a few suggestions. I always think, too, that our traders should pay considerably more attention to colonial requirements than they do, and think no trouble and expense given to "nursing" the first customer or two in any colony ill-spent. Probably for many years to come travellers in our colonies will have colossal distances to cover, and roads will annually improve a little, while railway extension will be slow. In twenty-five years it is possible that the English trade in motor cycles might only be a bagatelle compared to the colonial exports; and the question of catering for the colonies is not complicated by a call for a radically diverse specification. A machine that will suit the colonial rough rider will also suit the all weather, go anywhere home tourist: it is probably only in the height of the frame that the home machine need differ from the colonial.

The First Essential.

As far as I can make out, the first essential in a colonial machine is that it must be "fall-proof." I have often insisted that this feature is overlooked in the home market. Practically every motor bicycle in the country suffers at least one tumble annually; either it skids, or it is dropped when being wheeled, or the excited owner fails to prop it securely after a dismount. In the colonies frequent riding spills must be added to the list of falls we are liable to at home. When a man has to motor along 18in. bush bridle paths, interspersed with tree stumps and water troughs; when he has to push his mount out of nullahs and drifts; when he has to negotiate tracks made of undressed logs laid athwart his direction of travel, with here and there a log missing or rotted into powder, it is evident that an occasional tumble, and that a heavy one is inevitable.

Few machines on our home market are proof against this sort of experience. On some a low magneto bracket is the vulnerable point; on others the crank case (fancy a split crank case ruining your lubrication 100 miles from anywhere!); on many others the foot brake (with down grades of 1 in 3 ahead of you!); on almost all the foot-rests or foot plates (steel rods, a blow on which may twist the frame or rip the crank case; plates attached by light strip steel ties, which crumple up and compel you to wave one leg in the air for forty miles; aluminium plates, which crack in half, and so on); on some few machines the crankshaft or the variable gear is the vulnerable feature.

For home riding a machine that is "fall-proof" is certainly desirable; for colonial riding across huge tracks of lonely country bestrewn with grave difficulties, it is absolutely essential. Therefore the magneto should be placed in the safest position on the machine. Two sets of foot-rests should be provided, one pair of which should be so designed as to protect vital parts of the mechanism, without being so rigidly attached that damage to them means damage to the frame or engine.

The next prime essential is a sound variable gear. For home riding a machine may be termed a "good hill-climber" if it can rush a short length of 1 in 6 grade on a good surface under favourable conditions. Extremely bad hills are uncommon in England, and when the weather is bad we can usually make a detour. In some of our colonies grades of 1 in 3 are by no means uncommon when water courses have to be crossed, and, if short, they have to be negotiated from a standing start, over the worst of surfaces, and sometimes under a broiling sun. On plain main road hills grades of 1 in 5 and 1 in 6 are by no means rarities, and are combined with atrocious surfaces—loose sand, rough stones, and log roads, designed to avoid washouts in torrential rains. It may not be necessary that the machine should carry its rider up such phenomenal ascents; but I think it is necessary that the machine should be able to ascend a few yards of this combination of surface and gradient with the rider walking alongside; and few, if any, machines could accomplish even this without a change speed gear of some sort.

Districts where Repair Shops are Unknown.

Reliability of the highest order goes without saying in districts where repair shops are almost unknown, where spares have to be procured from thousands of miles away after delays of weeks, and where trains are infrequent and inaccessible. I think the next important special requirement of the colonial motor cyclist is better springing. It is by no means difficult to steer a motor bicycle over rough surfaces or along a narrow track. Eight years ago the road over the Grampians was in patches as bad a road as any living rider could keep in the saddle over; but, owing to its width, it was by no means impossible to cross it without a dismount. In the colonies riders occasionally strike several miles of road worse than the Grampian road has ever been, and only a foot or two in width, edged in maybe by trees or prickly plants. On such a road the standard English machine would bounce and buck like a frightened kangaroo, and the strongest combination of pluck and steel wrists would scarcely be able to hold it on the road. Imperfect spring forks and rigid saddle mountings can be of no service here, and possibly a completely sprung frame is an essential.

A NEW TRICAR LAMP.

AN acetylene lamp specially made for use on tricars has been introduced by the makers of the F.R.S. lamps and generators, Messrs. S. Hall and Sons, Ltd., 18-20, Swinton Row, Edinburgh. The body of this lamp is made of heavy gauge brass, it is 6in. in diameter over all, and has a Mangin lens of the finest quality, and, it is said, will illuminate the road for a distance of about 1,000 feet. Its weight is 6 lbs. The side sockets are brazed on from the under side of the body of the lamp as well as being riveted, and the catch for the door is of the invisible type as fitted to the motor bicycle lamp. The burner is adjustable as to height, angularity, and focus.

A

A REJUVENATED TRICAR.

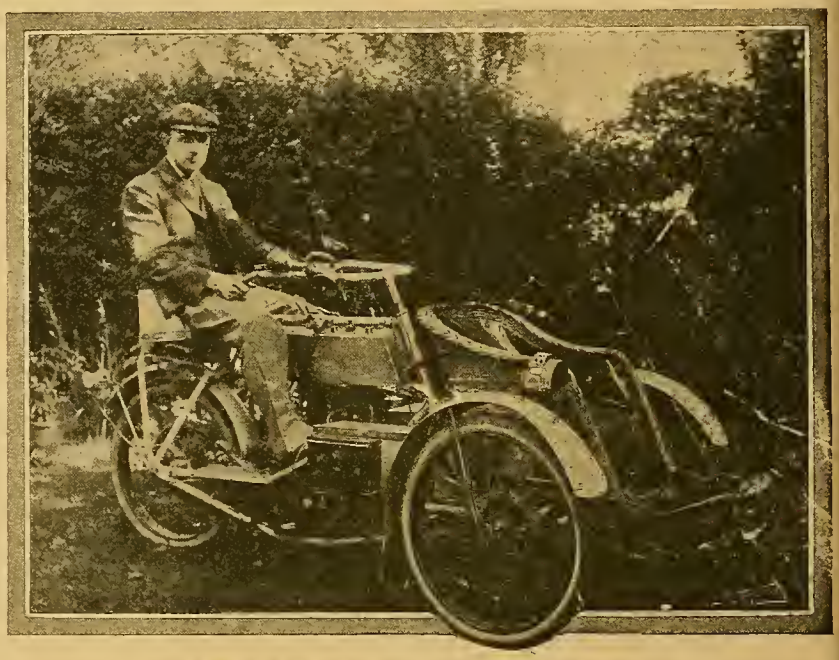
AS will be gathered from the annexed illustration, the subject of this article is a tricar which was first seen on the road in August, 1904. It is equipped with a 3½ h.p. (85 × 85 mm.) water-cooled M.M.C. engine, which by means of a chain drives a Bozier two-speed epicyclic gear fitted on a counter-shaft behind the engine, a second chain taking the drive from the gear box to the back wheel. The radiator is slung underneath the front axle, with the water tank behind it, a centrifugal pump being employed to assist in circulating the water. The brakes are powerful band brakes of large diameter, and the whole machine is very substantial. The ignition is by trembler coil and wipe contact.

Since the machine came into my hands, I have renewed the bushes in the engine bearings, and with the cylinder rebored and a new piston, timing wheels rekeyed, etc., the engine is in thorough order and running very well indeed. The tyres have been renewed, and a large tool box has been placed on the left side of the footboards, and a box containing accumulators and coil on the right.

Not the least improvements are the bucket seat in place of a saddle, and the long handle-bars. A steel frame has been fixed over the back wheel, and the seat is supported on it by four coil springs working on guide rods. The back of the seat is made of sheet tin built on to a wooden frame, the whole finished off with brass bands, and upholstered in American cloth. The seat gives a low position, and, with the springing, is very comfortable after a saddle. I may mention that anyone who owns a similar tricar could make the seat or have it made, and it is also suitable for a motor bicycle if the latter were provided with a two-speed gear and clutch. The whole is enamelled the colour of the machine, which is now French grey.

To lighten the machine, which was originally too heavy for the power of the engine, a wicker forecarriage has been substituted for a very heavy coach-built one.

On the road the machine has proved very reliable, and I have had some very good runs on it. As regards climbing, I have been over the mountain road from Festiniog to Bala. (I think that if the A.C.U. Six Days' Trials competitors had taken this road they would not have accomplished it too easily, and my passenger, a rider of a Triumph, agrees with me in this.) I have also been over the road from Denbigh to Pentre Voelas (highest point 1,550 feet above sea level). It is true I had to drop my passenger in one or two places, and also dismount myself in one place, but these were short stretches only, and I think the performance good for a 3½ h.p. engine, which did not overheat or show any sign of it on either of these excursions. My usual touring load is 22 stones, plus a portmanteau and some tools, the gear ratios being 7 to 1 and about 12½ to 1. The top gear is rather low, but with a fast running engine I find it quite high enough for my purpose.



A rejuvenated diamond frame tricar, first seen on the road six years ago.

With the above load the engine will run up to very high speeds on a favourable road, and there is no vibration from it whatever at its highest number of revolutions per minute. "All out," the pace must be very nearly thirty miles per hour, but twenty miles an hour is my usual touring speed. R. H. C.

MIXING THE MIXTURE.

SOME expert riders consider that one great defect of the average short inlet pipe and standard carburetter is that the petrol and air which form the explosive mixture do not get thoroughly mixed. If we could analyse the gas fed into the ordinary engine, we should probably find it is like badly made porridge—there are, as it were, lumps of crude petrol vapour floating in a thin stratum of neat air. One or two inventors have been at work for years on miniature fans, which are designed to be mounted horizontally over the jet, and to be revolved at a great rate by the engine suction. It sounds a simple matter to design such a fan, but if it is made lightly enough to work fast and well, it either soon wears out, or gets sucked up into the valve box by the fierce rush engendered by the piston at high speeds. Consequently most carburetter makers are content to fit a spraying cone, with milled surfaces, or else some other form of obstruction to the flow of the gases, which helps to mix up the petrol and air vapour more homogeneously. Here is a very simple makeshift, which I have found of distinct benefit. It consists merely of slipping into the inlet pipe a long spiral spring, the coils of which act as baffle plates to the rush of vapour, and, as shown by actual road results in timed sprint events, serve to stir up the vapour thoroughly. MELANGE.

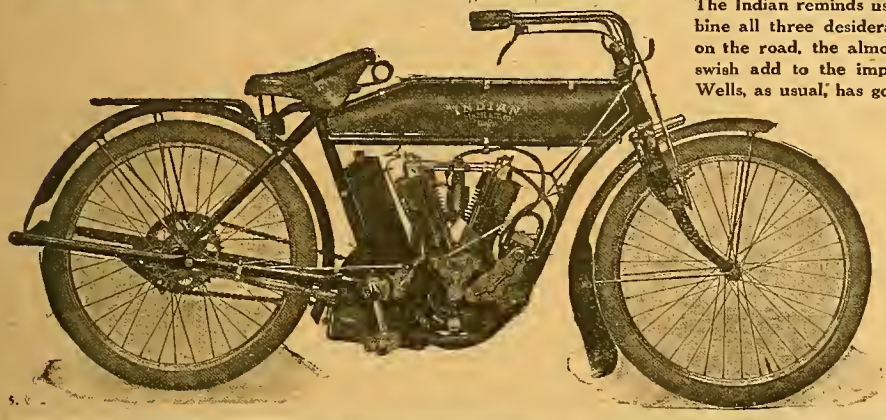
"Indian Motocycle" Hendee Manufacturing Co.

INDIAN



"Some Good Points in Design."

By B. H. DAVIES.

"The Indian is abnormally powerful (I mean in point of durability just now) in proportion to its weight. . . . Chain drive and low weight are already all to the good. . . . . Then the compound leverage of the valve gear is a good point. . . . . It does its work with an irreducible minimum of friction, and yet the timing can be correct to a hair. . . . . The moving parts of the engine are also exceptionally light—the most casual observer must note the compact neatness and ethereal proportions of the power unit, yet its prolonged speed in long distance records shows that the material is right. . . . . English makers abandoned 28in. wheels a few years ago, sacrificing some small amount of comfort and tyre longevity for a low saddle position. The Indian reminds us that it is possible to combine all three desiderata. . . . Seen and heard on the road, the almost silent exhaust and chain swish add to the impression of graceful motion. Wells, as usual, has got a good thing."

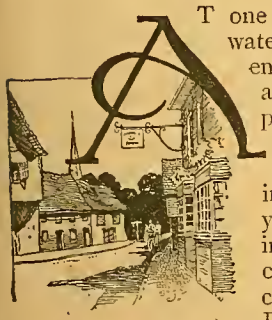
BROOKS B104 Anti-Vibratory Motor Cycle Saddle

WATER COOLING ON MOTOR BICYCLE ENGINES.

By "ROTATOR."



AT one time I scorned the idea of water cooling on motor bicycle engines, regarding the cooling apparatus as unnecessary complication, but, although I have ridden a score of different makes of motor cycles during the last seven or eight years, I am gradually inclining to the opinion that a water-cooled engine is the most efficient and satisfactory type. Realising the many drawbacks and difficulties in the way of water cooling a motor bicycle engine, I have seldom dared to venture the above opinion, so I was agreeably surprised to read in last week's issue of *The Motor Cycle* the article, "Water Cooling on Motor Bicycle Engines," and am interested to know that "Ailette" shares the same opinion as myself. I do not say that water cooling is bound to be adopted, or that it will be adopted in the near future, but unless some improvements are discovered in connection with air-cooled engines I feel convinced that the use of water jackets on motor bicycle engines will increase. Maybe a water-cooled cylinder head will be found sufficient. I have proved to my own satisfaction, and I think it is generally admitted, that a water-cooled engine retains its power more constantly than an air-cooled engine of the same size and design.

Obstacles in the Way of Water Cooling.

Recent converts may wonder why anyone can agitate for a water-cooled engine when air-cooled engines are so satisfactory. Unsightly radiators and water pipe connections, increased weight, and reduced petrol and oil capacity do not appeal to them. Of course, these are big obstacles to the use of water cooling, but, admitted that an air-cooled engine is extremely satisfactory, seasoned riders must agree that it has many shortcomings, and its chief defect, to my mind, is in the matter of wear. At one time it was said (and I believed it explicitly) that this abnormal wear of motor cycle engines was due to the fact that the workmanship and materials were not so good as in the case of cars. Of late years I have proved this statement to be entirely incorrect, for our best motor bicycle engines are every bit as carefully made of the best materials as the best car engine. Consequently we are left with the only deduction that this abnormal wear of motor cycle cylinders, pistons and piston rings, valves, etc., is due to an inherent defect of air cooling—that is, the great heat generated in a motor cycle engine. Fan cooling does not seem to have received the amount of attention and consideration it deserves, and there seems to be room for improvement in the casting of the radiating fins on seventy-five per cent. of present day engines. The combustion head is always the hottest part, but only on one or two engines are there an increased number of fins to radiate the excessive heat. I consider that large vertical fins with a clear passage for air currents to be absolutely necessary. Probably our makers have got a lot to learn yet in the selection of suitable metals for the great heat attained by air-cooled engines, and the excessive wear may shortly be counteracted. But there are other points in which an air-cooled engine falls short of the water-cooled type.

The Formation of Carbon.

Motor bicycle engines accumulate so much carbon deposit on the pistons and cylinder heads in less than a thousand miles that knocking manifests itself, and yet the best car engines are frequently untouched for four or five thousand miles. This constant removal of the cylinder is really a nuisance with motor cycle engines; it is not due to common oil, for the same thing happens with the very best oils, but is due to some extent to burning of the thick oil, high compression, and the fact that motor bicycle carburetters are placed in a much more exposed position than those on cars, resulting in road dust being sucked into the engine. But the trouble, again, seems to be chiefly due to the great heat motor cycle engines attain and wear of rings allowing the oil to leak past. The high temperature of motor cycle engines also accounts to a very large extent for the frequent breakage of exhaust valves and pitting of valve seatings, causing loss of compression. How often do valves of water-cooled engines break? Probably not one quarter so often as valves of air-cooled engines. Engine stiffness and sluggish starting are common complaints with some present day motor bicycle engines, but water-cooled engines hardly ever gum up, and in the majority of cases are ready to start at the first pull over with the handle even when cold. No motor bicycle seems to be up to date without a paraffin injection can to facilitate starting.

Of course, water cooling has its own particular disadvantages. There is the trouble of keeping the water in the tank at the right level (a hard working engine would soon cause the water in a thermo-syphon system to evaporate unless the water capacity was liberally arranged), the possibility of a cracked cylinder in frosty weather, leaky radiators, increased weight, etc. But the advent of water-cooled cylinders or combustion heads on motor bicycles would, in my opinion, sound the death knell of our four main troubles, viz., (1) overheating, (2) knocking, (3) excessive carbon deposits, and (4) valve breakages.

Improvement Still Needed.

My remarks, based on actual experience with both cars and motor cycles, prove that there is still room for improvement in design. Maybe the two-stroke engine will solve many of the difficulties, and I also think that some better method of releasing the exhaust gases of the four-stroke type could be found which would tend to keep the engine at a much lower temperature. Auxiliary exhaust release holes have been used for years with great success on track racing machines. The same idea on touring engines, but with a valve to open only on the exhaust stroke to keep the oil from escaping, is worth trying. I believe I am right in saying that a Coventry firm is building an engine on these lines for experimental purposes.

For fear my deductions may be misunderstood, I may add that I own and ride air-cooled machines, and I hope to continue to do so. I pen these few lines in the hope that designers may cudgel their fertile brains for the best means of artificial cooling.

A selection of questions of general interest received from readers and our replies thereto. All queries should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, E.C., and whether intended for publication or not, must be accompanied by a stamped addressed envelope for reply.

At Least 3½ h.p. for Sidecar Work.

I am about to invest in a 3 or 3½ h.p. single-cylinder N.S.U. Do you think it would be powerful enough for sidecar work, weight just over 20 stones all told? I should be quite satisfied with 12 to 15 m.p.h. and to help with the pedals uphill.—J. S. M

A 3½ h.p. with two-speed gear would be advisable for sidecar work. If you relied on one gear only you would frequently be called upon to assist with the pedals, and even then you could not climb steep hills.

Black Enamel for All Weathers.

I have ordered a new Triumph motor bicycle, but am very undecided whether to have it enamelled black all over including hubs, handlebars, wheels, spokes, etc., instead of plating. Do you think the enamel would wear as well as the nickel?—H.W.H.

It is entirely a matter for your personal choice. You would find enamel, if properly stoved, to last as long as plating. All-black machines are gaining favour on account of the difficulty of keeping the numerous plated parts of a motor bicycle bright.

Carburetter Flooding.

Can you tell me if there is anything unusual in the working of the carburetter on my four-cylinder F.N.? When the engine is running everything seems quite normal, but after stopping the engine the petrol overflows from the jet chamber at the junction of the auxiliary air-pipe, and continues for about fifteen seconds. I have had it overhauled by the makers, but the flooding continues as before. The needle valve fits accurately, and completely stops the flooding when the float has sunk to a certain point. Does this increase petrol consumption, and will it have any effect on the running of the engine?—S. K.

If the carburetter only floods for about fifteen seconds we should recommend you to leave matters as they are. A very minute quantity of petrol is lost, and if you touch the carburetter you may upset its adjustment. After stopping, take the needle between the first finger and thumb and twist it round, pressing it down at the same time. This will probably stop the flooding. If not, carefully read the article "Adjusting and Testing Carburetters" in this issue.

Swilling the Crank Case with Paraffin.

As I am taking the pedals off my machine, is it likely to harm the valve seatings or engine if, when I want to clean cylinder and crank case, I flood the latter with paraffin and run it on its own power a few hundred yards, repeating the process two or three times? Of course I should empty the crank case and refill each time.—R. W.

No, we should say that it is not advisable to run the engine on its own power when flooded with paraffin, especially if the bearings are at all a good fit, as seizure might possibly occur. If, however, you can start the engine by jacking up and pulling over the back wheel, you may run it for about five seconds, which is quite enough to cleanse the engine thoroughly.

A Two-speed Machine for Sidecar.

Please give me your unbiased opinion as to the suitability of the 1910 Phelon and Moore to take a sidecar. Myself and two friends have ordered them, two to be with sidecars. In choosing a machine I have had to have regard to the fact that I shall ride it a lot without the sidecar, and I therefore want something easily controllable in traffic and grease, as I am rather nervous of sideslip. My weight in riding clothes is fifteen stones. (1.) Will the Phelon and Moore take me alone up any hill such as Porlock or Lynton hills in Devonshire? (2.) Would it take a sidecarriage empty up these two hills with myself driving? (3.) Would it take an eight stone passenger up Rectory Hill, Amersham? (4.) Would it take me alone up Rectory Hill on top gear, and a sidecar with passenger up Barnet Hill on top gear? I may say I have ordered the standard sidecar gears of 5 and 9 to 1.—S.L.E.

We have had no experience with the 1910 P. and M., but we should say that (1) The machine, if in good order, would take you up the hills mentioned in your letter; of course, on the low gear. (2.) It would probably need a lower gear than standard with a sidecarriage, as your weight is above the ordinary. (3.) It should take a passenger up Rectory Hill, Amersham, easily. (4.) It certainly ought to take you up alone on top gear. If pulling really well, it might just take two up Barnet Hill on top gear. This hill is steeper than it looks near the top.

Cause of Engine Knocking.

(1.) Where can I get spare parts for 3 h.p. Clyde (Simms engine low tension), also (2) what is the cause of excessive knocking when encountering gradients? I use an Amac carburetter. Engine quite clean.—H.P.S.

(1.) You can get spare parts from Messrs. G. H. Wait and Co., Clyde Motor Works, Leicester, or perhaps from the Simms Magneto Co., Ltd., Welbeck Works, Kimberley Road, Willesden Lane, Kilburn, N.W. (2.) We suggest the following likely causes of the knocking: (1.) Possibly the engine may be over-geared. (2.) Some small part may be loose from wear. (3.) Through pre-ignition owing to the engine not having been cleaned internally for some time. (4.) Through pre-ignition owing to some derangement of the magneto timing mechanism.

A Difficulty in Starting.

I have just fitted a new magneto to my machine, but I cannot run it fast enough to get a proper spark to fire. The timing or setting is—the piston at the top of compression stroke, the advance lever retarded, and the points in the act of breaking. The engine and carburetter are all right, as they worked well with the accumulator. I can get a splendid and regular spark by turning the sprocket wheel smartly, when the driving chain is removed. I have no pedals or I might manage to rotate the magneto fast enough if on a stand. Do you think the magnets need remagnetising so as to give a good spark at slow speed?—J.B.

The fact that you can get a good spark when turning the armature with the fingers seems to show that the magneto is all right, and a spark is almost bound to occur when you wheel the machine along. Consequently, we should say that the refusal of the engine to fire is due to an imperfect mixture. It would be well to study previous hints in these columns on carburetter adjustment, and especially test whether too much air is entering *viâ* the main air intake. In cold weather the main air supply should be reduced to effect easy starting. The timing seems to be about right. If you still experience difficulty, consult the vendors of your magneto. The magnets should not need to be remagnetised if the magneto is a new one.

Timing a Twin.

Kindly advise me where the trouble lays in the timing of my 5 h.p. twin, Simms-Bosch magneto? I have timed the cylinders to fire just at the turn of firing stroke. The engine fires perfectly in this position with spark fully advanced, but when retarded over one notch it ceases to fire. I have taken plugs out, and find that they spark from advance to the retard, have also taken engine down and thoroughly overhauled it, regrinding valves, etc., and everything appears to be in perfect working order.—L.S.

As far as we can make out, the trouble with the timing is that the magneto is too much retarded. This is a sure sign if it ceases to fire when the lever is retarded. Try advancing the timing a very little at a time, and you will probably find that you will then get a full range of advance and retard.

Operating Pedals in the Dark.

I ride a 1909 Humber with footboards and foot levers. I find when riding in the dark that it is difficult, nay, impossible, to see the foot levers as one would desire. A small oil lamp fixed just behind the footboards (with a red rear glass) would throw a light on the levers of the machine generally. I should like to know if anyone has tried this, and his experience with it; also where such a lamp and fittings could be obtained. An ordinary cycle lamp would do, but that possesses no rear light.—N. W. D.

You could well rig up a lamp which would easily suit your purpose. It would be best to have an electric one. A small tricar or small car tail lamp would do. You could probably easily arrange to carry a small accumulator strapped to some convenient portion of the frame. Such a lamp or accumulator could be obtained from almost anyone dealing in accessories.

Drip Feed Lubricators.

I should be much obliged if you would tell me if a drip feed lubricator would be suitable to use with air-cooled oil on my 1909 Triumph. I have been told that during the cold weather the oil would not drip at all.—R. E. W.

If you refer to a drip feed or vacuum feed lubricator similar to the J.A.P or Rex, thick air-cooled oil will feed to the engine properly, but as oil is much thicker in winter than in summer, you would require to adjust the needle valve so that the oil flowed more readily to the crankcase. The two lubricators mentioned depend upon the vacuum created in the crankcase for feeding. That on the F.N. lightweight is placed below the level of the oil tank so that the oil merely runs into the crankcase *viâ* the lubricator, and the rate of feed is adjustable by a tap over the glass gauge. If you experience difficulty in getting the oil to flow properly, bear in mind that it is not necessary to use thick oil in winter; in fact, the makers of your engine recommend water-cooled oil for winter use.

Damage caused by Broken Rings.

If a piston ring breaks in the cylinder will it cause any damage to the cylinder if the engine is kept running? How can I tell when a ring is broken without removing the cylinder?—T. H. (Birkenhead).

A broken piston ring does not usually cause any damage to the cylinder unless a very small part breaks off, jams, and scores the cylinder. Loss of compression is the usual sign that a ring is broken, but it is not unusual when dismantling the engine to find a broken ring even when the engine has been previously running well. It is practically impossible to tell when a ring is broken without removing the cylinder.

The Effect of fitting a New Piston.

I recently had fitted to a 2¾ h.p. Humber engine (1904 pattern) a domed top piston with two rings—one at top and one at bottom. The engine does not run at all well, and I cannot get any speed out of it, and I am of opinion that this is caused by imperfect lubrication. Will boring holes in the sides of the piston improve matters, as I think the top ring does not get enough oil? I give the engine plenty of oil (Price's Motorine A). The domed top has increased the compression (it was formerly a low-compression engine). Do you think the higher compression advisable, or would a metal washer between cylinder and crank case be better? I find my machine will not climb hills as well as it ought to, considering I have a P. and M. two-speed gear 5¾ and 9½ to 1. This district is extremely hilly, and I fancy, with the engine in good order and these gears, I ought to be able to climb anything. The bearings are all right, the engine having recently been re-bushed; flywheels revolve freely, and do not rub against the crank case. The new piston is heavier than the old one, and I fancy the balance of the engine has been disturbed thereby. If the boring of holes as suggested is feasible, it would, I think, improve lubrication and balance of engine.—F. A. C.

Certainly you may try holes in the piston. This would reduce weight, improve lubrication, and possibly restore correct balance, but you would destroy the effect of the bottom ring, *i.e.*, you would be relying on the top ring only for compression. Perhaps the extra weight of the piston accounts for the sluggishness. Failing this, we should recommend you to fit a standard type of piston. Probably this will be the best way out of the difficulty, as the increased compression does not appear to be satisfactory with your machine. However, if you do not care to do this, try the metal washer and reduce the compression by this means. With a two-speed gear you certainly ought to be able to climb most hills, especially if the engine is properly adjusted and tuned up. An important point with old engines is to note that the exhaust valve lifts the full distance. Worn cams and weak valve springs account for loss of power.

Interchangeability of Tyres. Detachable Combustion Heads.

(1.) Please say if 26in. by 2½in. tyres will do for a rim which is made for 26in. by 2¼in. tyres? (2.) I want a two-speed twin for sidecar work, and notice that the Indian engine has detachable combustion heads. Are these better than the cylinder and head cast in one piece?—A.J.C., Gold Coast.

(1.) We know of no 2½in. cover which will fit a 2¼in. rim. (2.) Detachable combustion heads are a great advantage provided the joint between the head and cylinder can be made absolutely gastight. The chief advantages are that it is easy to bore the cylinder perfectly true, and to remove the combustion heads so that the carbon deposit may be readily removed.

Irregular Running.

After returning from a run and resting my machine for a few hours I tried to start it again on the stand (N.S.U. 3½ h.p., m.o.i.v., two-speed, 1906). After a good deal of pedalling, I got the engine to start, but it stopped in about two minutes, and after several injections and vigorous pedalling it would give a few explosions, and then stop. After repeating this several times, I began to test the different parts, and found the spark all right, the carburetter seemed all right, but the tappet on the inlet valve seemed to have a lot of play. I took the parts down, but all appeared in order. Can you please give me any advice? I have ridden a motor cycle six months, so am not very much experienced.—H.L.E.

You omit to mention the most important part, viz., the type of ignition. Your trouble sounds very much like a run down accumulator or a defect in the spark, as, if the machine came to a standstill with the engine running all right in the first instance nothing could derange itself while the machine was standing. Examine all the wiring carefully, also the switch handle and sparking plug points. If these prove to be in order, we should be inclined to think that the petrol pipe is choked up. Are you quite sure that the jet and petrol pipe are free? You can possibly tell if the irregular running is due to the petrol supply being impeded by holding up the needle valve when the engine is running. This causes a great deal more petrol to reach the jet. Finally, make sure that the inlet valve is opening and closing properly.

The Express Rubber Co., 19, Great Eastern Street, E.C., have lately placed on the market an excellent motor cycle suit, which, though it is well made and guaranteed for two years, is sold at a very moderate price. After examining this suit, which consists of a jacket and leg overalls, we have come to the conclusion that it is wonderfully good value. A capital waterproof coat and numerous other mackintosh articles of apparel are also sold, while, if desired, goods may be made to order. During this month the Express Rubber Co. are holding a sale, during which prices are substantially reduced.

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, E.C., and should be accompanied by the writer's full name and address.

The Use of the Carrier.

[4487.]—May I have the privilege of drawing attention, through the columns of your paper, to the danger of carrying a passenger on the carrier of some motor cycles. The makers of my machine informed me (at the Stanley Show) that the one they fitted was made of sufficient strength for this purpose, but I should like to warn my "colleagues of the wheel" that this has not proved to be the case with the machine supplied to me. Only this week a friend of mine was precipitated in the roadway owing to the two small rivets pulling out of the struts connecting the carrier with the back stays. Since the accident he has been compelled to remain at home owing to his face not being presentable, notwithstanding the fact that I was only driving at 12-14 m.p.h., and he only weighs just over nine stones. I am sure you will agree with me that this is a weak point to which attention should be drawn.

W. J. T. CREWE.

A Friendly Match.

[4488.]—I am quite willing to meet Mr. van Diggelen at the Brooklands Track if he particularly wishes the contest to be decided there. I should, however, be glad if he would agree to the event taking place at the Stadium, as the latter is quite safe for speeds up to sixty miles an hour, and is very accessible and sporting from the point of view of probable spectators. On Whit-Monday last the Western District M.C. (London), of which I am hon. secretary, held a meeting at the Stadium, and if, as I hope, a similar fixture is arranged this year, it would be very convenient and interesting if the challenge could be run off in conjunction. I agree to the distance of fifty miles, if so required by Mr. van Diggelen, though it seems to me unnecessarily long.

Mr. Geo. Brough, in letter 4476, is, I notice, also taking up the challenge. Perhaps, if that gentleman will communicate either with Mr. van Diggelen or with me, care of the Editor, the three of us could come to some definite arrangement.

F. H. MULLETT.

Improvements in Detail.

[4489.]—Regarding Mr. Lester's remarks under above heading in the issue of December 20th, I should like to say that it is an exaggeration to write that the valves of a Triumph often want grinding. I rode a 1909 model over 3,000 miles last year, and I am a heavyweight and rode up various test hills and never touched either valve. I can now stand on the pedal against compression for five minutes (perhaps more). After saying this, and also mentioning I have just ordered another machine of the same make, I may perhaps be permitted to offer a few criticisms on the new model.

(1.) The carrier is so shaped that the saddle cannot be put further back, therefore it has to be bent to allow such adjustment.

(2.) The footrests are rather too high, *i.e.*, near the seat. Both 1 and 2 only trouble a tall rider. 1 is easily obviated, the other is not, but does not much signify if the seat is further back.

(3.) The new toolbags are in an awkward position, but the company will supply the old style, so no "grumble" is fair on this score.

(4.) The inverted levers for exhaust and brake would be better replaced with ordinary pull-up ones.

These are all small points, and as an amateur rider I should like to add my humble praise to what I consider a practically perfect mount.

FRED STUART.

The A.C.U. and Provincial Clubs.

[4490.]—I notice Mr. Pickering is at it again, and I would like to ask him how many of his merry men have supported the A.C.U. trials?

I remember a scheme connected with military work also put forward by Mr. Pickering; how much have he and his merry men done towards *this* movement?

I remember he and his fellow committeemen passing a rule not to admit the trade to their club, the Worcestershire M.C.C. I should like to know how this has worked down his way. No doubt this accounts for the great gap between the 3,000 and 75,000.

I also see he is the hon. secretary of the A.C.U. Midland Centre, and I should like to know how much work he has done in his particular district.

I am asking these questions, because Mr. Pickering seems delighted in keeping the ball rolling at headquarters, and it all seems to end in smoke.

HAD SOME.

Road Dangers at Night.

[4491.]—Letter 4466 of the 20th ult., signed A. P. Board, appears to me to call for a little comment. Is it not impossible to expect a farmer to keep his herds at all times from straying one inch beyond the crown of the road?

I confess I do not understand how Mr. Board "inclined down hill," but I take it that on turning a corner he met some bullocks and charged them. Had the collision occurred a little later possibly the three ladies would have suffered instead of the bullocks. In a case of this description how would a lantern prevent a collision? The fault apparently lay with Mr. Board, in going too fast, either for his nerves or else for his stopping powers.

It also seems a trifle mean to impose on the good nature of people possessing more grit "by sitting down and awaiting a good Samaritan," although unhurt.

Given a suitable mount, one should hold his own in pace and still use discretion whenever there is not a clear view ahead. Some day, we may take to farming ourselves, and only then will some of us see such matters from both sides.

FRANK HALFORD.

Increase of Speed on Partially Raising the Exhaust Valve.

[4492.]—Does it not seem probable that the instantaneously created and enormous pressure caused by the explosion of the petrol vapour is not entirely relieved by the temporary opening of the exhaust valve? If this be the case when, in the ordinary course of events in the petrol engine, the exhaust valve closes, probably the pressure is not completely relieved. Therefore the next stroke (*i.e.*, the compression stroke) starts with some compression already existing. Thus when the exhaust valve is kept slightly raised—that is to say, when a continual escape of pressure is allowed—the result is an increase of power, temporarily at any rate. The explanation would appear to be that, although a certain amount of power is lost through a periodical partial loss of pressure, the total gain is greater than the loss when the forward pressure is not completely relieved. In a generalisation of this kind details are impossible. The solution would appear to be an increase in the size of the exhaust in proportion to the inlet valve, or a lengthening of the period of exhaust escape. The former seems to be the practical solution of the problem. Keeping the exhaust valve lifted is a practice which must lead to so much labour and damage to the engine in the way of grinding-in the valve that it cannot be recommended from any point of view except of those who make engines for people with unlimited incomes.

CHARLES WALKER, M.Sc.

American Records.

[4493.]—In reply to letter No. 4454, "American Records," it is quite good to note that the writer, Mr. S. Lacy Crolius, is so well pleased with *The Motor Cycle*.

With regard to records, however, and more particularly those of American origin, I beg to state that the Britisher has had some, thank you.

Has Mr. S. Lacy Crolius ever heard of a certain Dr. Cook who climbed Mount McKinley? (I don't think); and who also reached the North Pole? (Perhaps.) Those are American records, I presume.

I have a friend who owns a small four year old 6½ h.p. four-seater which was recently timed through a police trap of a quarter of a mile at the record speed of 42 m.p.h. There is a record for you, and timed by expert police who cannot err, of course, with 8s. 11d. stop watches guaranteed absolutely correct, of course. How is that for a record, American or otherwise?

We Britishers will be as glad as Mr. S. Lacy Crolius to see that big 7 h.p. racing motor cycle on our tracks and competing against our machines, and we Britishers promise not to swank until the race is run and the numbers are up.

COLONIAL.

Sidecars v. Tricars.

[4494.]—I have read the letter signed Henry Grafton in *The Motor Cycle* of December 27th, "Sidecars *v.* Tricars," and cannot say I can uphold the arguments in favour of the sidecar. Now I have driven a tricar for two years, and the only drawback I find is its unsociableness, which I do not count much when the benefits are taken into consideration. It is not very much better on a sidecar with pillbox silencers. The sidecar has many drawbacks: (1) Belt troubles (of course, if you have chain transmission with a 6 h.p. twin engine this takes you over seventy guineas); (2) driving round sharp corners dangerous; (3) transmission not evenly distributed; (4) uncomfortable riding position and steering, compared with nice comfortable sprung bucket seat and wheel steering; (5) bad for riding in traffic without a clutch, which, if fitted, would mean an increased price; (6) two wheels between forks instead of only one, causing more trouble in mending punctures; (7) tyre on driving wheel much too light for the work, causing endless trouble; (8) no saving in petrol consumption; (9) smallness of petrol tank for size of engine, generally only holding one and a quarter gallons instead of at least two gallons; (10) greater liability of a broken frame owing to extra driving strain.

H. A. TOMBLIN.

Lightweights v. Heavyweights.

[4495.]—Mr. B. G. Durkin's views on this subject make amusing but rather pathetic reading. One could have hoped that a six years' devotee to the hobby of motor cycling, as he professes himself to be, would have grown a little less narrow-minded. His little bit of bombast, too, about his "young, strong, nerved, and active" self, "revelling" in the speed and power of his twin, is typical of the sort of person one can imagine opening his throttle when he passes a broken-down motor cycle, to show how *he* can go. The spectacle of this gentleman sprinting about among the fat, middle-aged Benedicts who appear to form one section of his lightweight riding acquaintances must be extremely edifying, only, indeed, to be surpassed when he takes a day out with his other friends, the "weak, nerve-shattered, and aged" crowd that appears to "tremble" at the mere thought of bestriding his heavyweight.

The only point in his letter with which one can agree is that in which he says, "Different types of machine are intended for and used by absolutely different men." The fact is that the whole question of "Lightweights *v.* Heavyweights" is being looked upon from a wrong standpoint. It should not be the one *versus* the other. Each is used for its own peculiar adaptability to its own particular job, not necessarily its own particular man. For long-distance riding and touring few will deny that the heavy single or twin is the more suitable, while for dodging about from one village to another, with frequent stops, it is utterly unfitted. The "nervy" Mr. Durkin says "upholds" the heavyweight. Let him accompany a doctor on his round for one day, let him stop it and start it from the cold twenty times in the morning, and wheel it through narrow gateways and passages, and in and out of its own shed as often, and he will find he has as much "upholding" to do as even he can manage. In fact, there would be more "upholding" than he bargained for. It would be all "upholding," and by the end of a week he would wish he had two other "young, strong, active" men, and a boy, to help him "uphold" it, and would sigh for a light or medium weight machine to replace his speed king.

I speak from experience, having graduated from the 3½ h.p. heavyweight, through the 5 h.p. extra heavyweight twin, and tricar, to the 2¾ h.p. medium weight. I am neither fat, forty, nor married. I cannot place myself under the heading of weak, nerve-shattered, or aged, and yet I confess that, as a doctor, I find none of the first three come anywhere near the 1910 Douglas I got at the Stanley a few weeks ago. It is early yet to talk about reliability, but it does not take long to find out its handiness. I have so far gone about three hundred miles in all weathers, and find it a distinct success. With the Editor's leave, I will in a few months' time describe my experiences with it, including expenditure and upkeep.

(DR.) H. S. GASKELL.

[4496.]—In answer to Mr. W. L. T. Rhys's letter [No. 4464] in the issue of December 27th, in which he replies to Mr. Morris's letter, if he wants to talk about six days trials we will have a word to say here. He mentions the competition up Birdlip Hill during these trials, so we will take Birdlip first. Out of forty-nine competitors sixteen dismounted and five pedalled (all these were machines of 3½ h.p. downwards), and one surmounted this hill so well (though it was pedal-assisted) as to have "excellent" put after it. This was the 1¼ h.p. Motosacoche, which we do not claim to climb precipices without pedal assistance.

Now let us take Dinas Mawddwy. Thirty-two riders dismounted, a rider of a 7 h.p. machine included; eight machines were pedalled, the Motosacoche amongst them, again being marked "excellent." These figures are taken from the issue of *The Motor Cycle* of July 21st, 1909, page 542, and we think speak for themselves. Nobody in his sane senses would ever state that a 1¼ h.p. machine could travel as fast as a 3½ h.p. machine or upwards, nor did Mr. Case Morris infer such in his letter, we are sure, but what we say is that a Motosacoche will climb hills of 1 in 10 unaided, and with pedal assistance will go up hills which much more powerful motor cycles don't always surmount, and where a lot of them won't, even with pedal assistance. I think this was proved in the above trials, and we do not think Mr. Rhys could dispute this assertion after carefully considering it.

The other correspondent in the same issue, Mr. B. G. Durkin, hardly requires an answer, as he does not like lightweights on account, perhaps, of his being so young, as he says in his letter of the same date. Probably when he gets older he will begin to realise that people who ride lightweights are not so silly as he thinks they are.

MOTOSACOCHE, LTD.,
O. L. DE LISSA.

[4497.]—May I ask for a little space in your correspondence columns to explain the part of Mr. Karslake's letter [No. 4455] which refers to weights of Douglas machines taking part in the M.C.C. Consumption Trial last September.

The two machines ridden by Messrs. W. W. Douglas and Eli Clark weighed respectively, as stated, 122 and 124 lbs., these figures representing the weight of the machine, plus a very complete touring kit, lamp, and generator, spare clothing, etc.

The other two machines, weighing 145 and 150 lbs., were ridden by Mr. G. L. Fletcher and myself respectively, and were weighted up, carrying 40 and 45 lbs. dead weight, in order to benefit by a better petrol allowance, and, incidentally, making our performance better on formula.

It is noteworthy that the weighted machines secured second and third prizes (Mr. Fletcher's covering 133 miles to the gallon), despite this added weight and the adverse climatic conditions, rain falling the whole of the time, and the roads being in a very heavy condition, circumstances which are not propitious to low petrol consumption.

We are indebted to Mr. Karslake for giving us the opportunity of drawing attention to the very fine performance of lightweight machines carrying riders weighing over 11 stones plus 3 to 3½ stones of dead weight, and yet be capable of the performances recorded.

As Mr. Karslake was one of the officials presiding at the

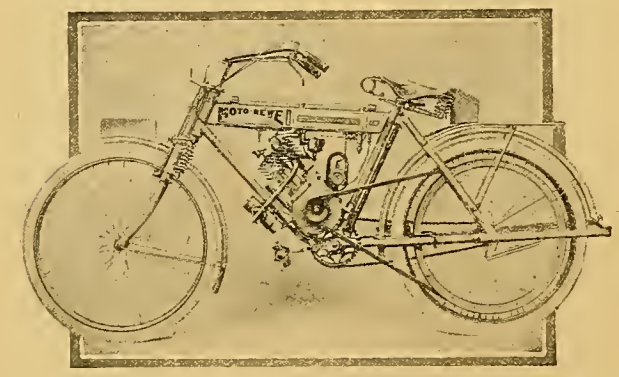
scales on the occasion of the M.C.C. trial, and it was patent to all present that the machines were carrying extra weight, it would tend to show that Mr. Karslake rushes into print without giving his subject very much consideration. A little reflection would have saved him making the very obvious error of assuming the weight of the Douglas to be 150 lbs.

For DOUGLAS BROS.,
J. V. ROBINSON, London Manager.

The Novel Piston Ring.

[4498.]—In reply to "S. T." [4457], December 27th, 1909, I am not aware that my invention has been in use for years, and "S.T." must have a greater knowledge than I have to make such a statement. A ring on similar lines was patented in 1903 (No. 20,258); if this is the one he refers to I quite agree with him that it would wear the cylinder unduly. The rings in above specification supported the piston; in fact, the rings carried the whole weight of the piston, which in my case would be entirely different. My patent agent, Mr. Samuel Hey, Keighley, made a search of over 1,500 specifications, and this specification (No. 20,258) was the only one touching upon my idea at all. Years ago how often was a cylinder lubricated? There were no pumps to feed the cylinder with oil as now. Any ring will wear the walls of a cylinder if it is not properly lubricated, but those that I have had running up to the present time are giving every satisfaction, and the wear so far as I can tell is no more than the ordinary ring.

I shall be pleased to hear from "S.T." on what engines he has seen my ring in use, as if he is basing his opinion of it from patent No. 20,258, and will study it and mine side by side, I think he will come to the conclusion that he has made a mistake. I thank "S.T." for his opinion and criticism, which I am very pleased to see, and hope next time he will sign his name in full. JOHN THOMAS.



1910 pattern single-cylinder Moto-Reve lightweight. The engine, which is rated at 1¾ h.p., measures 60 x 85 mm. The screened, yet accessible, positions of the carburetter and magneto will be noted. Transmission may be by round or V belt.

Belts on Lightweights.

[4499.]—I cannot refrain from making a few remarks on this subject, the recent correspondence has been so interesting and in some respects so irresistibly funny. I believe I have before stated that I am the owner of a 1907 Motosacoche.

"Engineer" [letter No. 4458] will, I think, find his trouble vanish to a great extent if he will get 4in. mudguards fitted, a hole being cut in the rear guard to allow the belt to travel through it. He will also find that 4in. mudguards keep the mud off more efficiently. But I heartily agree with him when he says there is not sufficient clearance, because the slack of the belt constantly hits the back tyre, as evidenced by the mark it leaves. He also says "belt unravelled at the ends." Ah, yes! so did mine in the old days. Let "Engineer" get 4in. mudguards, fit a 3½-4in. engine pulley, and apply a Watawata V belt, and he will be nearly happy!

In conclusion, Mr. de Lissa's assertion seems to have been expressed to more than one person at the Stanley Show. It is funny, but he told me about the "makers having brains." In fact, he gently hinted that others, like my bumble self, had no right to claim the possession of any contents within our cranium. FRANCIS J. GEOGHEGAN, M.D.

Two-speed Gears.

[4500.]—In reply to letter 4478 of January 3rd, we, as proprietors of the several patents of the gear in question (Griffin-Simplex), thank Mr. Jones for his kind intention, but would draw his attention particularly to the friction clutches in combination with the compound gearing, which are entirely new, and the most important feature of the gear.

A change-speed gear without an efficient friction clutch would not meet modern requirements, and we claim with our friction clutches as much slip as desired up to a positive lock, a unique method of control and change of speed combined in a very light and simple form.

Our latest design for 1910 as exhibited at the Stanley Show is a vast improvement on that illustrated on page 1018, Dec. 20th, 1909. Pinions are used instead of chains, there is no counter-shaft, the drive is entirely compensated, so no extra strain whatever is put on the engine-shaft, and the whole mechanism is enclosed in a small gearbox.

These additional features are fully covered in England and abroad, and are without doubt quite distinct from that illustrated on June 20th, 1904, which has not, however, come under our notice.

THE PATENT GEAR AND MOTOR CO.

Notification of Change of Ownership.

[4501.]—Acting on the advice given by you in your issue of December 27th, page 1030, regarding notification of change of ownership, I wrote the Middlesex County Council in reference to a Rex machine, which in 1908 the Service Co. took from me in part exchange for another machine. The Service Co. sold the Rex to another party after removing the numbers.

I was advised by those friends with whom I discussed the matter, subsequent to your publication of the advice, not to communicate with the authorities for fear of awakening a matter which otherwise might be allowed to lie dormant. However, I decided to risk it, and the enclosed is their reply. I believe there may be a large number of motor cyclists all over the country who are fearing to communicate with the authorities, and you would, I am sure, be doing a further good service by exhorting them to delay no longer. I have ascertained that the prosecutions are meant in real earnest. CHAS. S. LAKE.

[COPY.]

"Office of the Clerk of the County Council,
"Guildhall, Westminster, S.W.
"January 3rd, 1910.

"THE MOTOR CAR ACT, 1903. THE MOTOR CAR (REGISTRATION AND LICENSING) ORDER, 1903.

"Dear Sir,—I am in receipt of your letter of the 1st inst., as regards motor cycles H 3594 and H 4220.

"As regards H 3594, this registration is still standing in your name, no application having been received from you for the cancellation of the registration.

"I therefore enclose a form of application in order that you may apply for the cancellation of the registration.

"Yours respectfully,
"WALTER GEORGE AUSTIN,
"Clerk of the County Council.

"C. Lake, Esq.,
"5, Falkland Avenue,
"Church End, Finchley, N."

EXPERIENCES WANTED.

"S.K." (Warwick) would like readers' experiences with the Stewart speedometer on a motor cycle.

"Victor" (Knaresborough) would like readers' experiences with the Motosacoche, stating advantages and disadvantages.

"Rosamond" (Poulton-le-Fylde) would like readers' experiences with the 1¾ h.p. F.N., especially as regards hill-climbing, average speed, and behaviour of reducing gear.

NOTICE.

The Editor disclaims all legal responsibility in any way for loss of copy in the form of manuscript, drawings, or photographs submitted to him. Rejected manuscript, drawings, and photographs will only be returned provided a stamped addressed envelope is enclosed for the purpose.

Morgan's Internal Combustion Turbine.

SOME FURTHER CRITICISMS.

A great deal of interest has been created by the description and drawings of the Internal Combustion Turbine published on December 13th. The general opinion seems to be that there are great difficulties to overcome before this type of engine could be made to run properly and develop power. The patentee is, however, to be complimented on the manner in which he has worked out the idea, and although his design—if he decides to make it—may not be successful, it has aroused a considerable amount of criticism and comment of the greatest interest to mechanically-minded motor cyclists; comment which will assist others who may be conducting experiments in the same direction. Below we publish two further criticisms on this most interesting problem of the internal combustion turbine.

INCANDESCENT writes:

"I have been interested by the explosion turbine described and illustrated in the issue of December 13th, and wish to present a criticism and some remarks in the same spirit in which you present the design.

"The real vital objection to the principle is that there is no free escape for the products of combustion after the first reaction of the issuing jet is spent. Now if the outer bucket ring rotated and the buckets were made of reflex form there would be a true reaction, as in the Delavelle and Parsons turbines, and additional rings of revolving buckets could be added to make use of the expansion of the explosion charge.

"It will be seen that the only power available in the present design is that obtained from the impact of the issuing streams of mixture against the vanes of the stationary bucket ring, and that pressure existing in the space L (see drawings December 13th) can have no effect, as the pressure of this issuing stream from the burners cannot exceed that set up by the compressing piston. It is therefore clear that the machine would not run.

"If combustion took place in the space K at a moment when full compression was reached a far more violent impact upon the stationary vanes would result, but without some means of retaining the mixture in the space K until the moment of explosion the mixture would simply escape through the orifice of the jet or burner.

Mechanical Objections.

"Mechanically there are objections quite as vital. First, to be efficient the rotating portion would have to revolve several thousand turns per minute, necessitating a worm reducing gear. This high speed of rotation would completely upset the action of all the valves, as if the springs were weak enough to allow of their opening at slow speeds and when starting, they would allow the valves to open when the centrifugal force reached a certain value equal to the strength of the springs. Then, considering the heat and speed, the friction against the packing ring U would quickly put it out of business, and lubrication would be practically useless. The eccentric looks very nice in position shown between rollers, but when its major axis was vertical there would be a lot of slackness, and it would strike the opposite roller a hammer blow. In my opinion the speed of the revolving portion would completely upset the flow of petrol, as the centrifugal force would vary with the speed. Lastly, what position is the high-tension commutator to occupy? It will surely be required to carry the current to the sparking plugs.

"Any motor cyclist who is sufficiently interested in the problem of the turbine can gain a very great deal of useful information by spending a few hours in the South Kensington Patent Model Museum, where sectional models of the various reaction engines and turbines can be seen, many of them in actual operation. There is an enormous mass of difficulties, both operative and mechanical, to be overcome before an internal combustion turbine can be made to run and develop power, not the least of which is caused by the rapid loss of heat caused by expansion and conduction in the case of an explosive mixture as compared with steam.

"Probably the first success will be scored by a combination of the two forces by causing the intense heat of the explosions to take up water, which will thus be converted instantly into superheated steam, which will in turn act upon the buckets of the turbine. When one considers the enormous effect of the slightest leak in valves or piston of the reciprocating engine, together with the fact that in the turbine the surfaces of the vessels which contain the expanding gas cannot be allowed to come in contact, the difficulty of the proposition may be grasped by even the layman."

Another Criticism.

V. Grunwell says:

"With regard to the article on Morgan's internal combustion turbine in the issue of December 13th, I should like to point out what appear to me vital faults. I wish to state at the outset that I am not influenced by any wish to discourage either the inventor or others who feel disposed to test the idea by actual experiment.

"I cannot see how motion is to be obtained from the flame at the burners. The space in front of the latter is roughly triangular, and if we imagine the petrol and compressed air issuing from the burner, it is clear that when the mixture is fired it will expand in all directions, instead of being concentrated against the vanes.

"Turbines are simply means of utilising the momentum of moving gases or liquids by opposing a surface at an angle to the direction of motion, and which the moving body by its law of following a straight line endeavours to push or twist out of its path. It follows, then, that the moving body must have its motion directed in a straight line before meeting the vanes, and, further, that every effort should be made to raise the velocity to the highest point in that given direction. In the case of a turbine of this character the combustion must therefore take place before the gases reach the nozzle, otherwise all control over the direction of motion is lost.

Morgan's Internal Combustion Turbine.—

"The foregoing is to my mind quite a sufficient reason why the turbine would not operate without taking into account the destruction of the parts near the burners, the difficulties of adequate cooling (which would be very much greater than the inventor seems to imagine), and the apparent absence of control of petrol supply (which would be necessitated by the action of centrifugal force).

"It is, I believe, admitted that the great obstacle to the production of a successful internal combustion turbine is that of keeping the heat of the parts within working limits. Theoretically, heat is simply so much energy, and any dissipation of it is waste of power. The ordinary petrol or gas engine is by no means ideal in this respect, owing to the loss by radiation and by exhaust, but a compromise has had to be effected to get a practical machine. The steam engine approaches nearer to the ideal, as no radiation is necessary (the reverse is the case), the temperature of the steam not being so high as to exercise a destructive effect on the materials of which the parts of the engine are constructed.

"In case I should be accused of destructive criticism I will shortly forward the outline of an idea for meeting the various difficulties referred to above, which perhaps you may be disposed to insert in your valuable paper."

A Reply from the Patentee.

Mr. R. E. Morgan writes:

"I have read with great interest 'Engineer's' able criticism of my internal-combustion turbine, and would like to answer some of his objections. Perfect balance of the rotor may be obtained by having twin cylinders, side by side, for pumping, a cam for each, on the same shaft, the two cams being opposed. (I have shown this in the drawing of the same turbine designed for cars.) The two holes of the drum are cast from the same pattern, and the pistons would be similar also, so that the drum or rotor itself is easily balanced. The rim of the drum is a good fit on the vanes of the stator only, for a short distance on each side of the combustion chamber, the rest of the rim being relieved. The drum would be made a good tight fit in the outer shell (stator), and then 'run in' under its own power at the normal turbine speed till the vanes were a perfectly gastight fit without causing friction. Then they should not wear any further. The vanes, being thin, and inclined in the direction of rotation, presumably made of cast-iron, would spring to a certain extent, which spring would be aided by the pressure of the gases.

"'Engineer' says: 'It would be necessary always to use the sparking plugs to give the correct time of firing.' The delivery of the charge is continuous, and even with a single-cylinder pump the delivery of the charge would only be jerky at very low speeds. He imagines there to be a succession of charges at very short intervals instead of a continuous jet of combustible gas.

"The cooling water is sprayed, not into the combustion chamber, but on to the vanes, immediately after they have done their work, so I do not see how the sparking plugs can be affected. The plugs are made accessible by an inspection cover, which is placed on the side plate on the exhaust side. I did not show this in my drawings published in *The Motor Cycle* for fear of confusing the main idea with unnecessary details.

"With regard to the valves in the piston, the one valve acts against the other, so that the net result of the centrifugal force on the valves themselves is *nil*. The valve stems could be guided by lugs cast on the piston walls. A careful study of the action of the piston has made apparent to me that, if the valves were set rigidly on the same stem a certain distance apart, so that when one was fully shut the other was fully open, the movement of the valve seatings in the piston ends to and from the camshaft, and the inertia or momentum of the valve heads, would cause a perfectly timed automatic opening and closing of the valves. Thus a spring to hold them on their seatings is optional."

A PUZZLING CASE.

DURING one of the pleasant periods of last summer, after having covered several hundred miles in the early part of the week with almost monotonous reliability, I arrived home in South Lancashire on the Wednesday evening with rather a good opinion of the "irresistible combination," consisting of myself and a 1907 Triumph, fitted with several 1908 improvements.

Having the rest of the week to spare, suggestions for a good two days tour in North Wales, emanating from a pedal cycling brother, decided me upon a run for the Friday and Saturday.

Friday morning broke beautifully fine, and soon the "combination" was hopping along the Manchester-Warrington road. Now, on the previous Wednesday's run home mentioned above, I had, knowing that the route selected was an easy one, carefully burred over the jet of the B. and B. carburetter until a pin point would only enter about $\frac{1}{16}$in., and as a result the consumption of petrol for 140 miles had worked out at about one gallon, but, of course, the engine would take very little air, and hills had to be taken fast with a well-opened throttle. As far as Warrington the "combination" did great things, and as the engine purred along I theorised complacently on the subject of perfect proportion of jet to choke tube, etc.

My Path was Barred by a Gate.

Outside Warrington the path across the "silvery stream" that leads to Manchester was barred by a gate, and as I waited alongside a little single-cylinder car that snuffled and gurgled, a feeling of pity for "those people who know nothing about ignition" almost overwhelmed me. There was no doubt the engine of this little car was missing rather badly.

As the bridge swung back and the gate opened, "Old Misfire" and the "combination" started out over the undulating road to Chester. Here I came to the first hill of any note, so opening the throttle well the machine took the first half splendidly, when without any warning a feeling occurred as though someone had applied the brakes hard, or a bearing had seized, and almost before I could move a finger to do anything a terrific backfire sent the engine backwards and brought

A Puzzling Case.—

the machine to a sudden stop. Overheating. Perish the thought. I felt at the cylinder and found it no hotter than usual. Slipped magneto pinion. Now just at that moment the noise of a misfiring engine resounded in my ears. Never would I be caught by that little car. So with a heave and a run the exhaust valve was dropped. And, wonder of wonders, the "combination" finished the rest of the hill in fine style. As I rode quietly along theorising upon the effect of a very fine jet upon ignition, a brilliant thought struck me. All that had been done to cause this stop was a wide opening of the throttle. So waiting for a straight piece of road, the throttle was re-opened wide, the machine leaped forward, and was gaining speed rapidly when again the feeling occurred of brakes being applied, and before the throttle could be closed another backfire fetched me off all standing.

Finding that the central wire of the Oleo plug was loose, I soon had it out, and replaced it with an old spare of the same make. "Old Misfirer" having loomed in sight, I quickly stuffed the hot plug into my pocket, and was soon running into Chester.

A Beautiful Run into Llangollen.

Through Wrexham and Ruabon the pace was kept down by poor roads, but as the beautiful run into Llangollen was entered on the throttle was more generously opened and the pace increased. Suddenly the feeling of a brake being steadily applied and an alarming slowing down of the machine caused me to close the throttle, and the braking effect died away, the speed of the machine increasing again.

As I rode slowly into Llangollen a vow was registered that the cylinder and piston should be cleaned on arrival at Barmouth.

We will draw a veil over the run through Corwen, past the beautiful Bala Lake, and the wild road to Dolgelly. Suffice it to say that the trouble steadily grew worse, and that between Dolgelly and Barmouth the back-fire occurred about fifteen times, stopping me every time the throttle was opened more than about one-quarter.

After a hurried tea the cylinder was dismounted and examined carefully for any signs of a projecting piece of carbon deposit, but without any satisfaction. So after cleaning the piston and cylinder and carefully scraping the points of the plug I set out for a short run to test the result. In the first mile at each opening of the throttle back-fires stopped the machine dead, and in a very subdued frame of mind I rode slowly back into Barmouth. A cart blocking the way in the main street, I jerked the throttle open a bit to dart past. The next instant I found myself stopped suddenly with the carburetter on fire. That evening was spent in such a pre-occupied state of mind that after addressing four or five picture post-cards to a friend I posted them at a pillar box, and then remembered there were no stamps on. Next collection, 6 a.m.

Six o'clock next morning saw me hanging suspiciously round that pillar box to waylay the collector. After squaring this matter up the problem was again tackled as to how I was to do 170 miles that day over hilly roads on a machine that jibbed at every milepost on the road.

The garage was tackled for a new plug, but had no suitable ones. However, the proprietor kindly took a sparking plug out of one of his cars for me to try. A run of a few miles along the Dolgelly Road proved that this had entirely cured the trouble. Returning, I tried to buy that plug, but without success, so, making the best of a bad job, I carefully repacked the old plug and reduced the engine gear ratio to about 5 to 1 with an idea of climbing the hills with the throttle partly closed.

Proceeding quietly along the coast road to Harlech, I began to find that the engine would now stand the throttle well open on the hills, and turning sharply to the right at Portmadoc, the machine climbed the hill through the village splendidly, despite a very strong head wind. A short stop on the bridge at Aberglaslyn to admire the beautiful view proved to me that I had a stiff ride to tackle, for the wind was fairly lifting stones out of the road, and the rise is 700 feet in three miles to the Penygwrhyd Hotel. Without a falter the machine landed me at the hotel door, and here a short stop was made for refreshments, and the gear put back to 4¼ to 1.

A fast downhill run through Bethesda to Bangor proved a grand change to the performance of the day before, and I entered joyfully on the long pull against the wind through Conway, Colwyn Bay, and St. Asaph. After mistaking the route, and arriving in Denbigh when I was expecting to reach Mold, I got along finely and ran into Chester about five o'clock.

To my sorrow it proved to be Chester Cup day, and a push of half a mile through the crowd took a bit of the gilt off the gingerbread.

Home was reached about seven o'clock in the evening, the day's run having proved one of the best I have ever undertaken.

The Sequel.

Now comes the sequel. On Monday morning, having a journey of about four miles to make, I started off, and on the first long hill the back fire occurred no less than four times, stopping the machine each time. I had taken the precaution of carrying a new plug, and on putting this in, the trouble ceased, and has never occurred again.

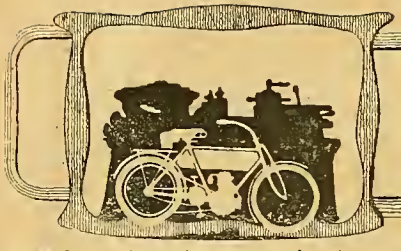
In this yarn I have tried to describe as well as possible the whole of the trouble, and it would be interesting to hear some other readers' ideas on what was the real cause of it.

Of course, we know it was the plug at fault, but where? Both plugs had done over one thousand miles, and were of a very reliable make, as I have run a similar plug five thousand miles without trouble.

I have satisfied myself of the cause, and should like to know if my opinion coincides with others of the fraternity.

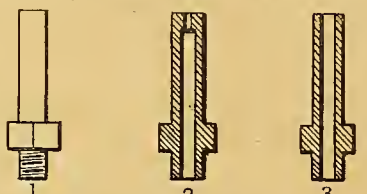
F. LUCAS.

Messrs. Priest and Co., 66, Bishop Street, Birmingham, inform us that they expect to place on the market very shortly a pocket flash lamp with two-volt woven glass accumulator, Osram metallic filament lamp, bull's-eye lens with adjustable focus and switch with metal cap to protect it. The production of this lamp has been inspired by a paragraph by "Road Rider" in *The Motor Cycle*, who recently wrote respecting the usefulness of an electric pocket flash-lamp. The size of the new lamp will be 4¼in. × 1⅞in. × ⅞in., and the weight a little over four ounces.



ADJUSTING and TESTING CARBURETTERS.

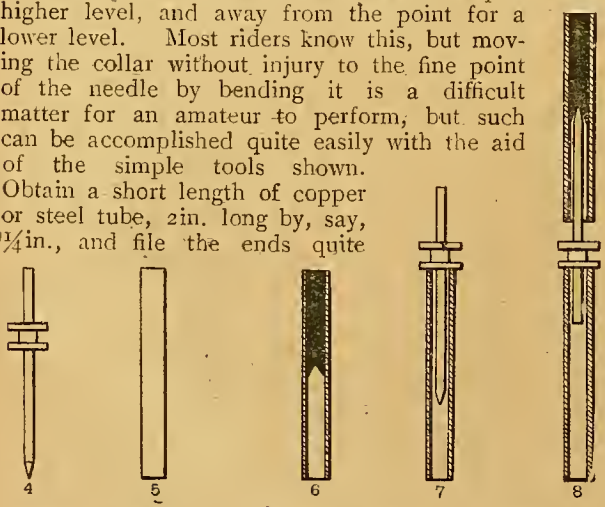
HOW often do we see in the questions and replies columns of *The Motor Cycle*, "Test the level of the petrol in the jet," etc., but how many riders know for certain to what height the level of the spirit rises in the majority of carburetters when *in situ*, for the very simple reason that the jet is inaccessible when in position on the machine. A casual glance at most machines will confirm this, and all intelligent riders will agree that the adjustment of the carburetter has a great deal to do with the satisfactory running of the engine. The accompanying drawings show a set of tools which will enable any intelligent reader to test the adjustment of the carburetter, also to carry out the necessary alterations if not correct. I refer to the predominant type of spray carburetter as used on motor cycles. Referring to the drawings, 1 shows a jet tube, 2 is the jet tube in section, and 3 is what is known as a dummy or testing jet tube. The latter is an ordinary jet tube as used in the carburetter, but drilled out as shown, so that one can readily see the level of the petrol spirit as it stands in the tube. It is obvious that it is impossible to see the level of the spirit in a standard jet by reason of the small size of the spraying hole in the top.



1 and 2—Ordinary jet tube.
3—Dummy or test tube.

Altering the Collar on the Needle.

Drawing 4 is the usual type of needle valve, and to alter the level of the petrol in the jet tube we move the collar shown on the needle nearer to the point for a higher level, and away from the point for a lower level. Most riders know this, but moving the collar without injury to the fine point of the needle by bending it is a difficult matter for an amateur to perform, but such can be accomplished quite easily with the aid of the simple tools shown. Obtain a short length of copper or steel tube, 2in. long by, say, ¼in., and file the ends quite true and square (5). A similar piece of tube 6 is partly filled with lead, the space occupied by the lead being shown black.

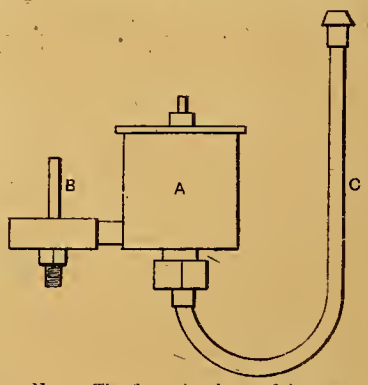


Needle valve and special tools employed for moving collar on needle valve.

Now, supposing we wish to reduce the level of the petrol in the jet tube, we place the needle in the tube 5 (as shown in sketch 7), and by tapping the top of the needle the point is caused to move away from the collar. When the float and needle are reassembled in the carburetter it will be found that the petrol is cut off earlier, and therefore does not mount to the same height in the jet tube as before. If it is desired to raise the level in the jet tube, we place the blunt end of the needle in tube 5, and the tube 6 over the end of the point (see sketch 8), and by tapping the end of tube 6 we move the point nearer the collar, thus raising the level of the petrol in the jet tube.

A Special Tool for the Needle.

The lead filled tube 6 can easily be made by plugging one end of the tube with a rivet or screw, heating the tube in a gas jet, and allowing a small stick of solder to melt and flow down the tube to the required depth. The tube should be first cleaned inside and a flux used to ensure all the solder adhering to the tube all over. After being filled with solder, a drill of the same diameter as the inside size of the tube should be run down the tube, so making a coned recess in the solder which ensures the needle point being kept central with the tube. Then when a blow is delivered on the top of the tube the needle point will bear evenly on the solder and prevent the needle springing a.d bending.



No. 9—The float chamber and jet tube connected to a special short petrol pipe ready for testing the level of the spirit in the jet tube.

Now comes the question, How is it possible to fix the carburetter in an easily accessible position, so that we can see the petrol in the test tube? Some carburetters can be turned at right angles to the usual position and held vertical while the petrol is turned on, but in cases where it cannot be so held we shall require a short piece of pipe and two unions the same size as those on the petrol pipe of the machine. The carburetter can then be fitted on the pipe as shown in the drawing No. 9, having the float chamber in an accessible position.

It is essential that the machine be supported vertically while these tests are being made, and that the float chamber is in the same vertical plane as the

Adjusting and Testing Carburetters.—

engine on the machine; the machine should rest on a level floor, and not be supported on the stand. The pipe supports the float chamber, which must be kept in an absolutely vertical position, which is easily obtained by bending the pipe. The drawing will show the method adopted. A represents the float chamber, B the test jet, and C the special pipe. Of course, the shape of the pipe will depend on the position of the petrol tap in the tank, but the one shown, a simple U-shaped pipe, will suit most machines.

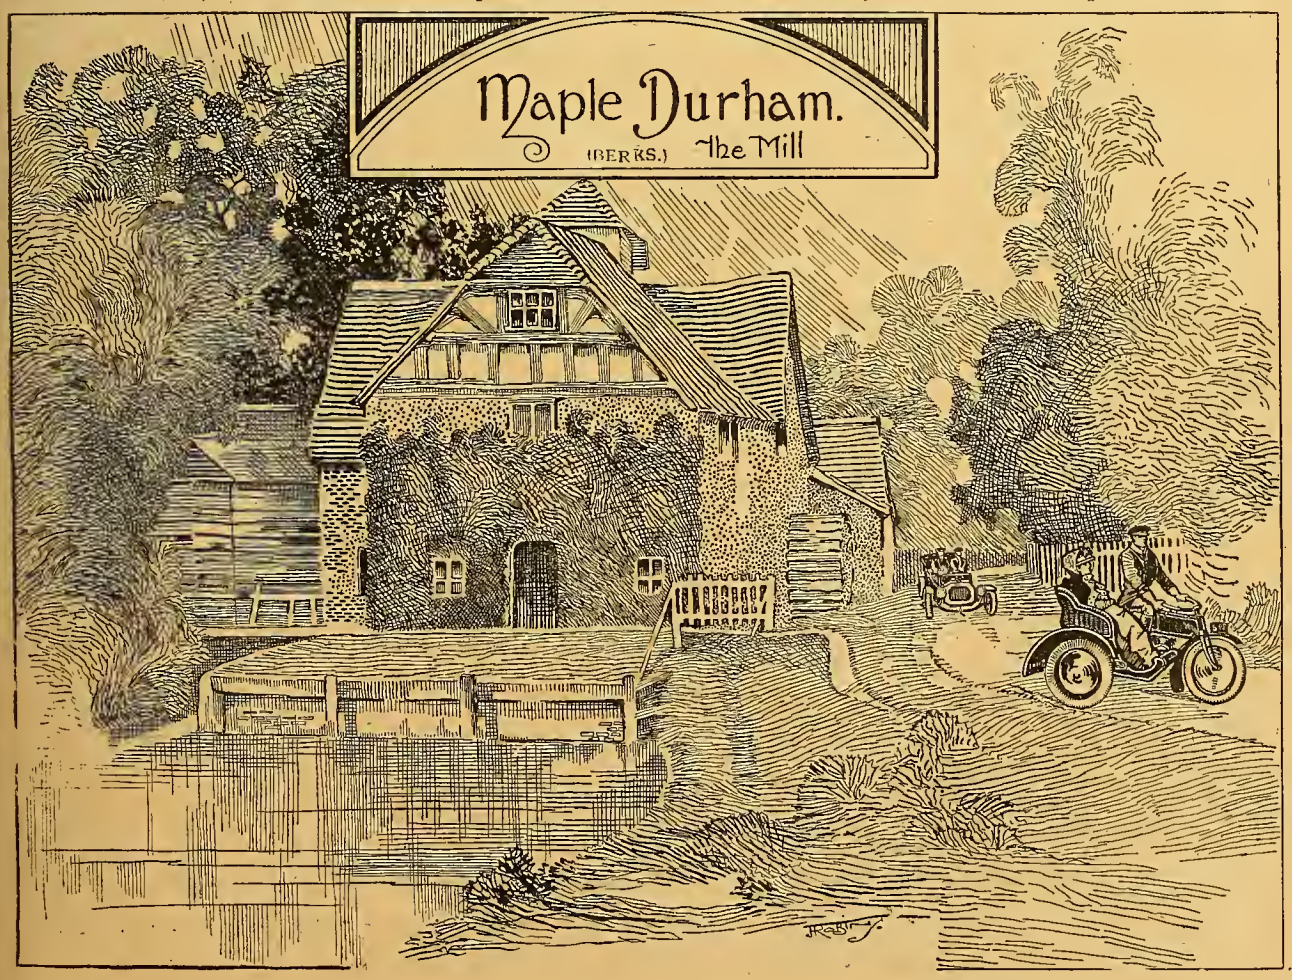
Before testing the carburetter, clean it out thoroughly and grind in the needle valve; also see that the balance weighted levers are free and working correctly, and that the float is not punctured.

When testing, turn on the petrol and allow it to run into the float chamber, but do not touch the needle; note the level of the petrol in the jet tube, then turn off petrol and drain the float chamber. Proceed as before, and see if the petrol rises to the same level twice in succession; if it does it is safe to assume that the float chamber is working satisfactorily, and that the spirit is cut off at the right time. If petrol drips from the carburetter it is usually an indication that the level is adjusted too high or the point of the needle requires regrinding. A little time and patience spent in testing the carburetter are well worth the extra trouble entailed, but if the job is a hurried one it often results in a false level, and consequent difficulty in starting from cold and loss of power on hills.

With the simple tools described in this article, testing carburetters will be rendered quite a simple job, and will also be very interesting to the rider who likes to know his machine. PILSI.

THE TRANSMISSION QUESTION.

ALTHOUGH advocates of chain transmission, and transmission by means of chain belts, have become more numerous lately, the ordinary V belt, especially of the rubber and canvas variety, has not been ousted by any means yet. Even for heavy passenger work belts are found quite satisfactory. The opinion of Mr. Vivian Olsson, the erstwhile holder of the End-to-end sidecar record, is interesting. It may be remembered that he used only one belt (a 1⅛in. Shamrock-Gloria) on his End-to-end trip, and since then he has run well over another 1,000 miles with the same belt on his 7 h.p. twin V.S. and sidecar. He says: "The S.G. belt is still in good condition and certainly good for at least a further 500 miles. When one can get belts that will take a heavy and powerful machine like mine plus sidecar for, say, 2,500 miles, those who advocate chains because they say belts are not strong enough seem to be a bit out. In every other respect, such as silence, smoothness of drive, etc., belts are already admitted to be superior to chains."



A33

Hints and Tips for Motor Cyclists.

By Road Rider.

SHARP-EDGED HANDLE-BAR FITTINGS.

327. I often wonder how much longer motor cyclists will put up with the spiky fitments attached to most handle-bars, especially on the clip of the exhaust valve lifting lever, and to a less degree on certain types of carburetter control. Many of these clips simply bristle with sharp edges and angles, and as a motor cycle is very frequently ridden with gloveless hands, these sharp edges abrade the skin of the fingers, and even rip the glove when gloves are worn. There is no really neat and presentable method of padding them either.

BAD ACCELERATION ON THE THROTTLE.

328. There are two main causes of an engine's seriously failing to respond when the throttle is opened. The first occurs only with a.o.i.v., and is due to the springs being weak or dirty. The second is bad mixture, which may result from using the wrong sizes of jet and air hole, so that there is an excess of petrol vapour when the throttle is slammed open; or may equally result from a long inlet pipe, or a pockety inlet pipe, full of bends and corners, in either of which pipes liquid petrol is apt to accumulate and cause a rush of rich mixture when the engine is accelerated.

POPPING BACK.

329. This is the name given to the sputtering puffs often heard in a badly adjusted carburetter, the back rush of which may be felt if the hand is laid over the extra air intake, and which often set a carburetter on fire (in this case turn off the petrol tap at once, and beat the flames out with your cap). The causes of this popping back are twofold. In rare instances the popping is due to wrong timing of the inlet valves, due to wrong meshing of the cog wheels, or to very weak springs, or a binding valve stem, each of which may allow the inlet valve to remain open during a part at least of the explosion stroke. The commoner cause is too weak a mixture. A weak mixture burns slowly, and is consequently still in a flaming condition when the properly timed inlet valve opens. Its flames ignite the fresh charge, which thereupon explodes prematurely, and blows back into the carburetter, so producing the popping noise described.

STARVING OF THE CARBURETTER.

330. Occasionally an engine will start off beautifully, but within a few yards begin to sputter, and quickly stop. If this behaviour is due to the carburetter, it is due to one of two things. Either freezing is in process; in this case it is probably necessary to warm the air supply, or to hot-air jacket the carburetter, but in some cases the removal of any gauze partitions in the inlet pipe may suffice, as freezing covers them with a film of snow. Or the supply of petrol is insufficient for the engine speed, owing to too small a jet, or obstructions in the petrol pipe, carburetter, or petrol filter. Reamering out the jet or cleaning the supply parts will effect a ready cure.

THE AMAC CARBURETTER.

331. A few of these carburetters appear to have been sent out with throttle springs which are not quite strong enough to keep the throttle valve down on its seat against the fierce suction of a good engine, with the result that the engine cannot be run slowly, nor stopped by pulling back the throttle lever. The makers will supply proper springs gratis. Some owners of these carburetters are ignorant how to adjust the petrol level. This is very simply done, as the needle valve spindle slides tightly in a brass tube of narrow bore, and its length may be altered by tapping it up and down in this brass tube. The adjustment of the lift of the two valves on these carburetters requires to be carefully done, and can only be verified with the racing type by testing the behaviour of the engine in actual running, though with the touring type the lift of the throttle valve can be seen when the inlet pipe union is detached. It should be remembered that adjustments are performed by the Bowden adjusting collars at the handle-bar ends of the wires. Screwing these collars out from the bracket *increases* the lift of the valves, and *vice versâ*.

TWINS STARTING ON ONE CYLINDER ONLY.

332. If once in a way a twin-cylinder engine starts on one cylinder only, the other chipping in after a few yards, the explanation may be any kind of temporary defect in the reluctant cylinder. But if as a general rule the engine starts on one cylinder only, the most probable reason is that the spring of one of the automatic inlet valves is stronger than the other or the valve sticks on its seat. The two inlet valves should be taken out, and the ends of the stems pressed together; the valve which opens first has the weaker spring, and its spring should be increased to the strength of the stronger one. If both springs are too strong, the engine will be very difficult to start. A strong spring may be reduced by cutting off a coil, by filing off some of the depth of the cotter, or by holding the spring compressed in a vice or spanner for a few hours.

BADLY SOLDERED PETROL UNIONS.

333. One of the most awkward mishaps to put right by the roadside is a coned petrol union which has come unsoldered from its pipe. Directions have been previously given for patching up a makeshift union with string wrapping and soap or seccotine, but such a makeshift joint cannot last long, and the rider's best plan is to make sure that the unions are properly soldered. Before a long trial the writer invariably disconnects the petrol unions, and remakes them, and, except on a few first-class makes, he often finds the joint is only held by a "wire" of solder. The end of the pipe butts into a socket on the coned union, which is a good ¼in. in depth, and the coat of solder should be the full depth of this socket. This ideal can probably only be attained by thinly coating the end of the pipe for ¼in. all round with solder, heating the coned socket, thrusting the pipe in carefully and centrally (so as not to squeeze off the soft solder on to the rim of the union), and finally by repeated applications of heat, flux, and solder, running the joint full up with solder. If such a joint has to be remade, and the rider cannot do it himself, he should insist on standing over the mechanic, and assuring himself that pipe and union are soldered for the whole of the ¼in. by which they overlap. Otherwise trouble is probable.

CONVERTING OBSOLETE MACHINES.

334. Owners of prehistoric machines, fitted with such sound engines as the M.M.C., Buchet, De Dion, Excelsior, etc., should realise that the obsolete high frame is probably the worst portion of the machine, as the lofty position of the rider makes the machine liable to skid. Now, a frame is the cheapest item among the main components of a motor bicycle, and a brand new low frame, such as the Chater Lea No. 6, is quite inexpensive, while from sales of bankrupt stock and the like a complete low frame can often be picked up for an old song. If the engine and fittings of the old machine be reassembled on such a frame, the machine will be infinitely pleasanter to ride. Other desirable details, such as a modern carburetter and a pair of spring fork attachments and a belt rim brake, may similarly be obtained by the astute buyer for very small sums. They often figure in the miscellaneous advertisement columns of *The Motor Cycle* at quite nominal prices. In particular the new frame will make it possible to use a large diameter belt-rim of correct angle with an adjustable pulley, and the fitting of a ⅞in. or ¾in. belt will reduce trouble considerably. No doubt what the owners of ancient machines chiefly desire is a high-tension magneto, but these are neither cheap to buy nor easy to fit. I should rather recommend a first-rate single-cylinder make and break contact breaker of large dimensions, with substantial adjustments, to be substituted for the small and flimsy pear-shaped device previously employed. These are almost as reliable as the magneto contact breaker. The accumulator box may then be lined with sheet rubber seccotined in place, and all the holes by which wires emerge from the tank carefully lined with rubber. For £5 or so a 1903 machine may thus be transformed into a far more reliable and comfortable mount, and when it is desired to dispose of it, the new mount will command a proportionately higher figure. The great point is not to hurry one's detail purchases, but to wait until the parts required are advertised at a bargain price.

WRITE FOR PARTICULARS OF

THE

SCOTT

PATENT NON-SKID
MOTOR CYCLE TREAD.

"The alternate steel and rubber studded Tyre."

Will not skid on wet or dry roads.

J. LIVERSIDGE & SON, LTD. Chief Office: 196, OLD STREET. ESTABLISHED OVER FIFTY YEARS.

SCOTT

TWO STROKE. FREE ENGINE.
TWO SPEEDS. CHAIN DRIVE.
TWO-CYLINDER. SELF-STARTER.

"The Car," Oct. 6th, 1909, in commenting upon the Tourist Trophy Race, says: "A point which probably appealed more to the public than anything else was the sensational start of the Scott machine, with two-speed gear and clutch, which enabled it to move off the mark with great celerity, and without effort on the part of the driver."

The Scott Two-speed Gear and Free Engine

is the only chain-driven, two-speed machine on the market fitted with a frictionless gear. There are no phosphor bronze or wearing materials embodied in its construction, and the whole mechanism being of high grade, case-hardened steel, the gears may be slipped and changed as frequently as desired without any wear or renewal of parts at any time. Remember—there are no gear wheels—simply two expanding clutches, and it is the only gear fitted with a central drive. Further, it has no overhung bearings.

The All-weather, Go-anywhere Machine.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns—9d. per line of 8 words; minimum, two lines. Name and address must be counted. Thus—

Two lines (16 words or less) costs 1/6
Three lines (24 words or less) costs 2/3
Four lines (32 words or less) costs 3/-

In the case of Trade Advertisements a series of thirteen insertions is charged as twelve.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor Street, E.C.), on Tuesday morning previous to the date of issue.

When possible advertisements received at Coventry on the Wednesday will be inserted.

All letters relating to advertisement should state distinctly under what heading and in what issue the announcement appeared.

CLASSIFICATION BY LOCALITY.

For the convenience of purchasers of second-hand motor cycles, the advertisements are classified into districts, as many readers like to know what machines are for sale in their immediate neighbourhood before going further afield.

Wauchope's Brilliant Lead-off for 1910.

WAUCHOPE'S, 9, Shoe Lane, Fleet Street, London, E.C., is a house where you can deal with perfect confidence You can at all times rely upon Wauchope's treating your interests identically as they would their own, and experience has taught you that you cannot quite say the same of everybody.

WAUCHOPE'S, 9, Shoe Lane, Fleet Street, London, E.C., do not merely supply new motor cycles of the leading and most reliable makes in the market, but they supply these constantly in the course of their business. This house does not gain your trust to-day, and lose it to-morrow. Why? Because they lend their name and reputation to such things only as will enhance esteem on the part of their friends, and convince them that at **WAUCHOPE'S** honesty is before halfpence!

WAUCHOPE'S, 9, Shoe Lane, Fleet Street, London, E.C., have a special reputation attaching itself to that part of their business which is so favourably and popularly known as their exchange system. By this splendidly useful method of dealing, on the part of this house, there is really no such thing as a worthless machine. Every machine possesses in itself a certain cash value, so that your old machine becomes an asset towards the part payment of your new one. The wisdom and fairness of this style of trading is beyond all praise.

WAUCHOPE'S, 9, Shoe Lane, Fleet Street, London, E.C., never curtail their customers on the point of selection. The fact of the matter is that at **WAUCHOPE'S** you find a range of choice which you cannot discover elsewhere. These goods are no mere "decoy ducks," but are really excellent machines, all ready for the road, and guaranteed to the purchaser. When you get **WAUCHOPE'S Guarantee** over a transaction, you find that such a warranty is a guarantee in fact and deed; not a mere verbiage of words which are meant to be meaningless. If you have dealt at **WAUCHOPE'S,** you know this already.

WAUCHOPE'S, 9, Shoe Lane, Fleet Street, London, E.C. have some genuine specimens of art and utility in second-hand Triumph Motor Cycles, free engine, and direct drive models. They are also showing others on two-speed gear principle at prices ranging from £12 10s. We will feel sorry if circumstances prevent your honouring us with a personal inspection of these magnificent goods; but if such a call really cannot be managed, we sincerely request that, in your own interests, you will write us, and thus afford us an opportunity of sending you full particulars by post, with our characteristic promptitude.

WAUCHOPE'S, 9, Shoe Lane, Fleet Street, London, E.C., are showing some bargains really worth looking at in 1909 BRAND NEW MOTOR CYCLES. This, to "the man in the street," is one of the chances of a lifetime, and life is too short to omit such an opportunity. These motor cycles emanate from the leading manufacturing houses, and the reputation of the makers is more than a guarantee for their excellence. Please note that **WAUCHOPE'S** are offering them at sacrificial prices, and we are confident that if you miss seeing these, or getting to know all about them, you will miss a value very hard to recoup, and equally rarely obtainable!

WAUCHOPE'S, 9, Shoe Lane, Fleet Street, London, E.C., would very specially invite the practical attention of all competent judges to their admirably finished Second-hand Roadsters, ranging from £8 10s. and upwards. To all on the outlook for machines where style, workmanship, and condition are paramount features, these machines possess a very special value. They are thoroughly sound and perfect, and are of such a character as to do hard work, and to do it thoroughly. They may be at all times implicitly relied upon on the road to perform their part of the work, with unswerving accuracy and faultless satisfaction. This is a line which will quickly disappear from a purchaser's opportunity, and accordingly reason dictates that the sooner the opportunity is seen to and adopted, the better will it be all round for the purchasers themselves.

WAUCHOPE'S, 9, Shoe Lane, Fleet Street, London, E.C., are never "cribbed, cabined, and confined," in the selections which they offer; and in this year of grace 1910 Wauchope's are, in this important aspect and feature of their enterprise, in a better position than ever. This is saying much, but a visit and inspection of the lines exposed for sale will, we confidently state, more than fully justify the assertion, there being on hand at the present date a stock of no fewer than 200 NEW AND SECOND-HAND MOTOR CYCLES on submission for the selection of buyers who know and appreciate what genuine worth and merit really mean!

WAUCHOPE'S, 9, Shoe Lane, Fleet Street, London, E.C., in the ordinary conduct of their business take care that every machine carries its own guarantee of fitness and excellence. This has ever been the principle of **WAUCHOPE'S** during the years which are gone, and it will continue to be throughout the time to come; and that all their patrons, new and old, may enjoy a thoroughly happy and prosperous season is the sincere wish of

WAUCHOPE'S, 9, SHOE LANE, FLEET ST., LONDON. E.C.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, 2d. will be charged for registration, and three stamped and addressed envelopes must be sent for forwarding replies. Only the number will appear in the advertisement. Replies should be addressed, "No. 000, c/o 'The Motor Cycle,' Coventry"; or if "London" is added to the address, then to the number given, c/o "The Motor Cycle," 20, Tudor Street, E.C.

DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt, and upon intimation of the arrival and acceptance of the goods, the money is forwarded less a charge of 1s. for registration. The time allowed for a decision after receipt of the goods is three days, and if no sale is effected, each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe and Sons Limited.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

MOTOR BICYCLES FOR SALE.

SECTION I.

Northumberland, Cumberland, Durham, and Westmoreland.

5½h.p. Twin Rex, magneto, spring forks, new adjustable pulley, rubber studded tyres, equal new, spring cantilever seat, B100 saddle, Roc free engine clutch, handle starting, twin back tyres, absolute non-skid, acetylene lamp; bargain, £24.—4, Thorburn St., Fulwell, Sunderland.

SECTION II.

York and Lancashire.

CROSS for Triumphs in Rotherham. 1910 model in stock; order early; £48 15s.

1906 Minerva Twin, Bosch magneto, Brown and Barlow, spring forks and seat; £25.—Cross, Triumph Agent, Rotherham.

1910 Ariel, Douglas, Bradbury, Norton, F.N., Indian, Premier, N.S.U.—Gourlay, Fallowfield.

1909 Rex, guaranteed perfect, only minus pedal; offers—Coates, Ellerton, Richmond, Yorks.

2¾h.p. De Dion, Chater-Lea, 26in. wheels, good condition; £7 10s.—Simpkin, 5, Link St., Longsight.

2h.p. Humber, chain drive, splendid condition, new tyre back, front good.—Tinsley, Fulford, York.

VINDEC, 5h.p., magneto, twin Truffault forks, perfect order; £23, or offer.—39, Bell Hall Terrace, Halifax.

1909 Triumph, fine condition, little used, Mabon clutch, new re-treaded back; £39.—Walker, Church Lane, Liverpool.

2½h.p. Ariel Lightweight, good running condition, accumulator; cheap, £9. — Botterill, St. James's Chambers, Harrogate.

1909 Triumph, 3½h.p., standard model, brand new as unpacked; £38 cash.—Moldgreen Engineering Wks., Huddersfield.

1908 N.S.U., 3½h.p., magneto, 1910 Mabon free engine clutch, ridden 200 miles; owner's health cause of selling; reasonable offer.—Write, Alwyn, 29, Malsir Rd., Keighley.

1909 Triumph, guaranteed, grand condition, little used, searchlight lamp, tools and spares, splendid hill-climber, new August; £36.—White, 60, Bank St., Mexborough.

1910 Rex, 3½h.p., tourist model, immediate delivery from stock, with all latest improvements; exchanges entertained.—F. C. Jones and Co., 3, Redeross St., Liverpool.

BIGGEST Bargain ever offered.—3½h.p. Quadrant, in good running order, complete with belt, coil, accumulator, horn, tool bag, number plates; £4 19s. 9d.—Booth's Motories, Halifax.

TRIUMPH, late 1909, Cowey, Lucas headlight, Premo shock absorber, spares, not done 2,000, as new; £42, or near offer; seen by appointment; no exchange; owner buying car.—Heywood, 86, Clyde Rd., W. Didsbury.

1909 F.E. Triumph, only been run 2,000 miles, good condition, Glare headlight, Cowey speedometer, nearly new Dunlop non-skids; best offer accepted for immediate sale.—Samter, 55, Palatine Rd., Withington, Manchester.

MOTOR BICYCLES FOR SALE.

LEPHANT Motor Mart.—5h.p. 1907 Twin Rex, £11; 5h.p. twin Bercley, £12 10s.; 2½h.p. Ormonde. 2h.p. Minerva, £5; Singer tricar, magneto, £7; we , sell, or exchange motors and goods; state wants.

LEPHANT.—Sole London Agents for 1910 Coventry Arno; £45; delivery from stock; liberal exchanges. 0 and 12, Elephant Rd., London.

.p. M.M.C., Chater-Lea No. 6 frame, Davison's tank, petrol gauge, Palmer cord, footboards; £16. hange lower power and cash.—H.S., 33, St. Stephen's , Bow, E.

ERRY (Sarolea), 2½h.p., Chater frame, Brooks saddle, Dunlop tyre, £5; Whittle belt, 9s. 6d.; nel belt, 7s. 6d.; Moseley cover (new), 10s. 6d.—130, xton Rd., S.W.

1h.p. N.S.U. Twin Lightweight, new last September, 2 lamp, horn, handle-bar mirror, watch, spare er and belt; £34.—Crook, 38, Ashchurch Park Villas, pherd's Bush.

INERVA, 1908, 3½h.p., magneto, spring forks, non-skids, adjustable pulley, splendid condition; £20.—Kenmure Rd., Mare St., Hackney, London. Great bar- n; must sell.

OC Clutch and two-speed geared 3½h.p. motor cycle spring forks, H.B. control, low, just overhauled reliable; £16, must sell.—619, Lea Bridge Rd rton, London.

1h.p. Vindec Special, Bosch magneto, B. and B., H.B 2 control, Truffault forks, Dermatine, adjustable ley, low, in good condition; £17.—E. Mawer, 104, sham Rd., Putney.

.N., 5-6h.p., done one season, perfect condition, handle-bar control, footrests, practically new tyres, re Michelin non-skid, Brooks bags, spares, etc.; £35. enton, Rickmansworth.

ARGAIN.—3½h.p. Stevens, overhead mechanical valves, guaranteed new condition throughout; n for debt; no use to owner; £12 10s.—Boot Shop High St., Putney, S.W.

WIN Rex, November, 1909, not been 50 miles spares, lamp, horn, two belts; offers; exchange h.p. 2-cyl. tricar.—Box No. L884, *The Motor Cycle* ces. 20, Tudor St., E.C.

08 2½h.p. Magneto Rex Lightweight, Brown and Barlow carburetter, handle-bar control, every- g absolutely as new, guaranteed; £17, or nearest —35 Arlington Rd., Surbiton.

.h.p. Rex, fine condition, Longuemare, good climber tyres good, unpunctured back B100 saddle, low tion, comfortable; sacrifice £8, appointment.—E. E. ker, 241, High St., Brentford.

N., 5-6h.p., 1909 model, perfect condition, tyres tools, accessories, etc., complete; on view 106, Gt land St.; £35—Preston, St. George's House, East- p. Owner leaving for Australia.

h.p. Twin Peugeot, 1908 model, had very little use original tyres, also everything in first-rate order; t have room; sacrifice £15.—Owner, 4, Westbury lene, Hanger Lane, Ealing, W.

G. FENN'S Speed King Rex, 1909 machine, 1910 twin engine, new condition, latest improvements; rts invited; sacrifice £28 for quick sale.—Apply 7 Mortimer Market, Tottenham Court Rd., W.

h.p. Minerva, 1909, not ridden 400 miles, Mabon clutch, variable pulley, splendid machine, as new. l spares; £25, cash bargain; sidecarriage, Mills, up ered, Bates band, £4, perfect.—S. Blenkern, 58, rwell Rd., Beckenham.

ANTON'S Bradbury, 1909, winner several gold medals, equal to new, specially tuned up, unpunc ml R.O.M. tyres; take £30, with lamp, tools, spares, ssories, finest machine on road.—619, Lea Bridge Rd. on, London.

S.U., 1908, 3h.p., magneto, M.O.V., fine hill-climber fast, reliable as clock; £15, to clear.—Stanton ew.

YL. F.N., 4½h.p., and nearly new Chater-Lea sidecar all spares and accessories, absolutely perfect con- ltn; take £26 to clear.—Stanton, 619, Lea Bridge Rd Leyton, London.

E Bargain of the week (29).—2½h.p. Peugeot (just been rebushed), vertical engine, 26in. wheels, new elin back cover, long handle-bars, low saddle ion, fast, powerful, horn, toolbag, stand, two new Continental tubes.—12, Market Sq., Horsham x.

RGAIN, £20.—4½h.p. Roc, two-speed gear, Roc clutch, magneto ignition, spring fork, Dunlop tyres fitted with iron studded hand, very powerful ma- h, take any hill with sidecar; also Millford sidecar, od condition. £5.—Write, S.R., 46, Regent St., Lon- W.

09 Chater No. 6 Frame, 5h.p. twin Rex, magneto Amac carburetter, handle-bar control, latest ion free engine clutch, adjustable pulley, lin- 7tle, foot brake, accessories, mirror headlight, rous spares, fitted Chater sidecar, headlight, per- ct £28.—Letters, 28, Siddons Rd., Tottenham, N.

EARANCE.—2½h.p. Kerry, £8 10s.; 6h.p. twin An- toine, £17 10s.; 2½h.p. Brown, £8 10s.; 2½h.p urant, £4 10s.; 2½h.p. J.A.P., £8 10s.; 2½h.p. Phœ- ix magneto two speeds, £14 10s.; Rex de Luxe, clutch neto, twin, £20; ditto, £25; exchanges; please call rite; trials.—128, High Rd., Tottenham. 'Phone, 9, Tottenham.

CAMEL

Franco-British Exhibition 1908.

3 *Grand Prix.* 8 *Gold Medals.*

As a chain is only as strong as its weakest link, a belt is only as efficient as its least considered essential.

The essential links in motor belting construction—Maximum effective pulling surface; Elimination of stretch; Tensile strength; Flexibility; Centring of core; Prevention of twisting, ends breaking, and surface cracking—when evenly considered and supported by suitable materials and experience, ensure a perfect whole.

Camel Belting, owing to its uniform wear, due to scientific construction, is offered and sold as being the nearest possible to the ideal.

Obtainable through all Agents.

A PUBLIC LETTER OF APOLOGY.

Jan. 10th, 1910.

Lancashire Motor Exchange,
Euston Road,
Morecambe.

Dear Reader,

I feel called upon to publicly apologize for delay in answering, and at the same time thank the very kind people who have written me this Xmas wishing me success in the coming year, and stating that I am filling a long felt want, also making remarks of a very personal character against the trade as carried on by some dealers. With whom, by the by, I have no connections.

Then again, I wish to publicly thank the riders who competed for the Lincoln Elk, and beg to state that I hope by now to have got off the much delayed presents. This, by the by, has been caused by the extra rush in getting off the Xmas orders for Moto-Reves and other machines, also by the heavy consignments of new 1910 models I have received. I must not forget the extra heavy Mail Bag each post has brought, which in itself is an enormous strain on my clerical staff. However, in the coming year I shall be able to deal more effectively with the correspondence, as I have engaged another first-class typewriter and shorthand clerk. Before closing, let me press upon you the fact that I am at all times pleased to hear from you; even if you have written once and for any reason our deal fell through, write again! I will repeat what one secretary of a cycling club wrote: Members of our club are seeking a firm who are prepared to deal square and who can supply a reliable article at a reasonable price, and are not buyers of the cheap rubbish on the market. I hope I shall fill that want, as cheap rubbish I will not touch. I will wish you all a prosperous New Year, and hope your kind wishes to me will come true. Don't forget new Bargain List, also Moto-Reve specifications now ready. See my advts. in "Motor Cycling."

Yours respectfully,
C. H. HITCHEN.

ADDRESS—20, TUDOR STREET, LONDON, E.C.

A MOTOR CYCLIST'S VIEWS FROM THE STATES.

MR. EARLE L. OVINGTON, a well-known American motor cyclist whose name is not unfamiliar to our readers, has lately been spending some time in Europe. On the occasion of a chat with him the other day he gave us a good deal of information about motor cycling in the United States. First of all, the conversation dealt with the amateur question. T. K. Hastings, it will be remembered, was made a professional last year by the Federation of American Motor Cyclists because in the 1908 Land's End to John-o'-Groat's trial he competed against English trade riders. This at first sounds strange, but it must be remembered that the American amateur definition is different from ours.

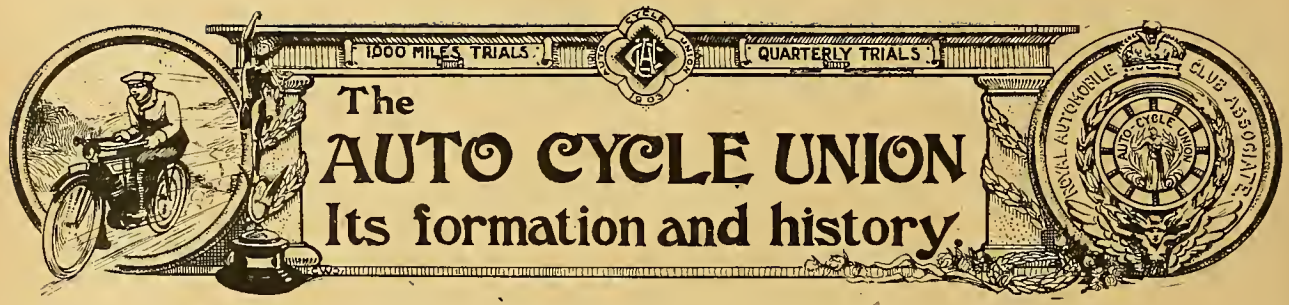
It must be understood, then, that the F.A.M. recognises three classes of riders: (1) The professional, who is employed exclusively in riding motor cycles for money or for the purpose of winning money. (2) The trade rider, a man not wholly occupied in motor cycling, though undoubtedly an expert exponent of the pastime, who may be occupied in another business, and yet receives machines or parts either free of charge or at reduced terms, or who has a machine loaned to him by a maker. (3) The amateur who rides purely for pleasure, and who receives no outside assistance from the trade in any shape or form.

These, then, are the three classes of riders recognised by the F.A.M., and very rigidly is the rule in which these classes occur observed. No man who transgresses the amateur rule either in the spirit or the letter is considered an amateur by any other sporting body. Mr. Ovington, who would dearly like to compete in our End-to-end trial, fears that by so doing he would be disqualified by the Amateur Athletic Union, and be prevented from taking part in competitions as an amateur were he to be proved otherwise by the F.A.M.

At present it is impossible to say whether the British governing body of motor cycling will take up the same attitude as the American one, but in the meantime it is hard that its restrictions prevent their countrymen from taking part in British competitions; in any case the difficulty does not seem to be an insuperable one. Surely at its next annual general meeting the F.A.M. could pass a rule rendering American competitors subservient to the motor cycle laws of the country in which they compete.

We next tackled Mr. Ovington on the question of American records being recognised in this country. He was certainly somewhat sore at the attitude the English motor cycling community takes up in this direction, as he assured us that in all cases the timing was most carefully carried out. On the Florida Beach, for instance, he positively refused to admit the possibility of error, as in this case the times were recorded electrically. However, he agreed that there should be a special committee to appoint official timekeepers provided with approved chronometers, which should periodically be tested by the Government.

Mr. Ovington is a very keen motor cyclist and a thorough sportsman, and he is most anxious that American motor cyclists should meet their English *confrères* on their own ground, and he has returned to the States with the object of doing his best to persuade the principal manufacturers to send a team to compete with our best riders at Brooklands.



The AUTO CYCLE UNION
Its formation and history.

IN 1903, when the number of motor cyclists was rapidly increasing, and there was every indication that the pastime of motor cycling would not only live but prosper, there was no ruling body to govern the sport. Early, however, in that year—in January, in fact—there was formed an Advisory Committee of the Automobile Club of Great Britain and Ireland (now the Royal Automobile Club), consisting of Mr. Roger W. Wallace, K.C., Messrs. M. G. Duncan, Basil H. Joy, J. Rennell, E. R. Shipton, C. A. Smith, Robert Todd, Mervyn O'Gorman, Dr. Whitehall Cooke, Charles Jarrott, and the Rev. Arundel Whatton. Soon afterwards, Mr. Arthur Candler, now the hon. secretary of the Motor Cycling Club, was elected a member. This committee then advised the Royal Automobile Club on any matter appertaining to motor cycling, but in April of the same year the committee founded the Auto Cycle Club, which took over the control of the pastime from the Automobile Club.

An Important Meeting.

In the first year of its existence the Club did excellent work. One of its first deeds was to put before the Government the status of the motor cycle, and for this purpose the Auto Cycle Club invited to a meeting representatives of the National Cyclists' Union and the Cyclists' Touring Club, with a view to making suggestions to the Local Government Board. The secretary, Mr. F. Straight, had several satisfactory interviews with the Local Government Board officials, who adopted practically the whole of the suggestions made, among which, we may mention, was one to provide motor cycles with specially small number plates. Another result of this interview was to fix the weight of a motor cycle for the purpose of registration at 3 cwts. unladen.

From time to time, the Inland Revenue tax has attracted the attention of the Club, and in the first year of its existence it fought a case which was of great importance. The Recorder at Bristol had dismissed a summons against a motor cyclist for not paying the 15s. Inland Revenue tax, holding that a motor cycle was not a carriage within the meaning of the Act. The Inland Revenue authorities appealed, and the matter was referred to the King's Bench. Though the Club, with the assistance of Mr. Robert Todd (chairman), engaged counsel to fight the case, it found, unfortunately, that, owing to the terms in which the magistrates had stated this particular case, it was impossible to proceed.

H.S.H. Prince Francis of Teck, K.C.V.O., D.S.O., the president.
(Photograph by W. S. Stuart, Richmond.)

Another important case fought by the A.C.C. was that of a motor cyclist summoned for riding a motor bicycle without exhibiting a rear light. Mr. Todd again took up the cudgels for the Club, and was successful in getting the case dismissed. Attempts were also made to mitigate the dangerous practice of tramway companies excessively watering their tracks.

Motor Cycle Racing.

Prior to the formation of the Auto Cycle Club motor cycle racing had not been organised, but on the formation of the Club, when the National Cyclists' Union had handed over the control of the sport to the Automobile Club and the Automobile Club had passed over the control to the Auto Cycle Club, the last named body undertook the registration of racing motor cyclists, and 280 certificates were issued during the Club's first year. Without these certificates it was impossible for a motor cyclist to compete in any open competition in England, and it is interesting to note that the certificate was, and is, recognised by the Irish Cyclists' Union and the Scottish Cyclists' Union, and, in consequence, any rider suspended by the Auto Cycle Union is ineligible to take part in any race held throughout Great Britain and Ireland.

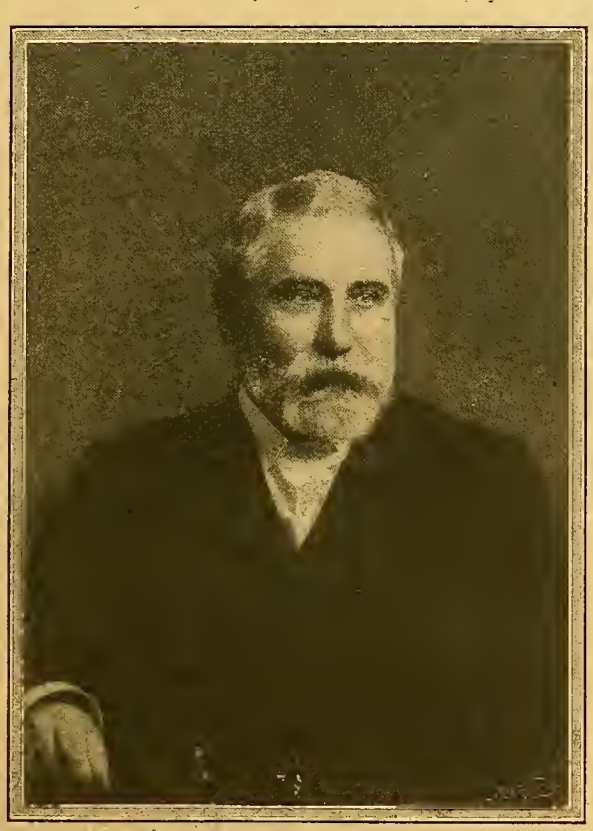
The Club also issued permits to various bodies to hold motor cycle races in different parts of the country,

the object of which was to see that these races were properly carried out, and that the performances made therein would be official.

The Gordon Bennett Race Week.

The first competitions to be carried out by the Club were races at Phœnix Park, Dublin, and Castlewellan, during the week in which the Gordon-Bennett Race was held in Ireland, and in addition a successful meeting was held at the Crystal Palace, when a race was held for *The Motor Cycle* Challenge Cup. This was won by J. F. Crundall, on a 2 h.p. 70 × 70 mm. Humber, and two other cups competed for were won by riders on machines with engines limited to 76 × 76 mm. The result of this meeting was that for all ordinary tracks the larger limit was established and for inferior grass tracks the smaller limit was imposed.

In 1903, also, the first 1,000 Miles Trial for motor cycles ever held in this country took place under the auspices of the Auto Cycle Club, starting from the Crystal Palace. Motor cycles were also first used for military purposes, when the Club was asked by Lieut.-Colonel Mayhew to obtain the services of a number of motor cyclists for the army manœuvres. In the same year, interesting papers were also instituted, and among these we may mention "Improvements in the Motor Cycle" by Mr. Mervyn O'Gorman, and "The Care of Accumulators" by Mr. D. Elyard Brown. Later in the year it was announced that the Club had instituted an affiliation scheme, by which motor cycle clubs throughout the country could have a voice in the control of the sport and assist in any movement for the benefit of the pastime.



Mr. Robert Todd, chairman and a vice-president.

In the next year of its existence, viz., 1904, the Club promoted a Side-slip Trial, in which various interesting devices were tested, and later on carried out a Hill-climbing Competition, followed in August by a most successful 1,000 Miles Trial. This year, instead of starting from a centre, the trial took the form of a tour.

The International Motor Cycle Cup Race.

At very short notice the Club sent a team of riders to represent England in the International Cup Race, held in France near Dourdan. France, Germany, Austria, and Denmark were represented. Unfortunately, owing to nails having been maliciously placed upon the course on one side of the road, the English competitors stood no chance, and as a result of the action taken by the Club, the Automobile Club of France offered five hundred francs for the discovery of the offenders. The Club held its first Consumption Trial in October, and later on in the season held the first Tricar Trial for machines designed to carry two passengers and fitted with a variable speed gear. The Club elected witnesses to give evidence before the Local Government Board as to the suggested speed limits in the City of London, and also at Kingston (Surrey), and in each case the proposition was successful, while through the Hon. J. Scott Montagu, now Lord Montagu, the Club approached the Chancellor of the Exchequer and urged the inclusion of a clause in the next Finance Bill excluding motor cycles from the category of taxable carriages.

An arrangement was also entered into with the Motor Union whereby the Auto Cycle Club was affiliated to the Motor Union on advantageous terms. At the end of 1904 the membership was nearly doubled, and on completion of the scheme several clubs became affiliated.

In the third year of its existence (1905) the A.C.U. entered into a new scheme with the Motor Union whereby all clubs affiliated to the former body were also affiliated to the Motor Union. In the same year the Club became affiliated to the Fédération Internationale des Clubs Moto Cyclistes, now defunct.

Race in the Isle of Man.

In connection with the International Cup Race, an Eliminating Trial was held in the Isle of Man, while the actual race was held in France. It is interesting to note that the British team was the only complete team to finish the course.

The affiliation scheme continued to prosper, and a further number of clubs joined.

A most successful hill-climb was carried out in the grounds of the late Sir F. S. Phillipson Stow, near Haslemere, and in August the Six Days Trial was held in the form of a tour through the West and South of England. It is interesting to note that in the 1904 trial forty-five machines started and nineteen finished, and in the following year thirty-one machines started and twenty-two finished. Two Members' Penalty Runs were promoted during the active riding season, one in May and the other in September, the latter being exceedingly well supported. A Consumption Trial was also held.

The last reliability trial of the year was a Tricar Trial, a most successful affair, which took place over the Uxbridge-Banbury-Uxbridge route, now adopted for the Quarterly Trials. During this year arrangements were made with the French Customs authorities whereby members of the Club could, on presentation

History of the A.C.U.—

Mr. H. P. E. Harding.

of their membership ticket, take their machines into France without payment of duty.

The Land's End to John-o'-Groat's Trial.

In 1906 the Club continued to prosper, and many private members and members of affiliated clubs took advantage of the numerous touring facilities offered, while clubs to the number of twenty-five helped to swell its ranks, and its total membership reached 1,620. The first great trial from Land's End to John-o'-Groat's took place this year, and for it an entry of ninety-three was received; seventy started, and thirty-six competitors reached John-o'-Groat's. The Penalty Run proved to be very successful and intensely popular.

This year the Eliminating Trials for the International Cup Race were held, by kind permission of Lord Derby, on his estate at Knowsley Park, Lancashire, and in the actual race, which was held in Austria, C. R. Collier, the English rider, finished third. The race, however, was not all that could be desired, since the Austrian competitors had men riding round the course carrying spare tyres and parts. As this was a breach of the rules, a protest was lodged by the English delegates on the conclusion of the race, and this was the last occasion on which the International Cup Race was run.

Birdlip Hill-climbing Competition.

A most successful hill-climb was held in September up the well-known acclivity known as Birdlip Hill, seventy-five entries being received. The last competition of the year was a combined Passenger and Consumption Trial, held in conjunction with the Quarterly Trial in October, the first of these popular events being run in April, 1906. In this year a new Club badge was designed to fix to the handle-bars of a machine, and it was decided, in order to bring provincial members in closer contact with headquarters, that it would be useful to appoint honorary representatives in each district. A permit was granted to the Brooklands Automobile Racing Club to enable it to promote motor cycle events.

In February, 1907, the Club held a series of Silencer Trials at the Clément-Talbot Works, and some interesting results were obtained. In May in that year the first Tourist Trophy Race under a fuel consumption limit was held in the Isle of Man for a handsome trophy presented by the Marquis de Mouzilly St. Mars. A Penalty Run was also held in provincial centres for affiliated clubs, but in most centres it had to be abandoned through lack of support, and finally it was decided to discontinue it. A council meeting was held at Lincoln in September, at which it was decided to recommend that the Auto Cycle Club should itself do the work then carried out by the Motor Union. At the end of this year the working arrangement entered into with the Motor Union in January, 1905, came to an end, and at the beginning of the following year the Motor Union seceded from the Royal Automobile Club. It was at the meeting at Lincoln that it was decided to call the Auto Cycle Club in future the Auto Cycle Union.

Mr. J. W. G. Brooker.

Mr. H. Gillard Cove.

History of the A.C.U.—

The question of again appealing to the Chancellor of the Exchequer for reduction in the Inland Revenue tax for motor cyclists was the subject of some correspondence with Lord Montagu of Beaulieu, who, however, did not hold out much hope of success. However, a deputation of representatives of the Royal Automobile Club, among whom was Mr. Robert Todd representing the Auto Cycle Union, consulted with the Chancellor of the Exchequer, with the result that the tax on motor bicycles was kept down to the lowest possible limit.

Mr. F. Straight, secretary of the A.C.U. since its inception.

The Lightweight Question.

During the history of the A.C.U., Mr. A. J. Wilson consistently endeavoured to improve the lightweight motor bicycle by presenting medals, etc., for competition, and in 1907 this type of machine had so far justified itself that several further prizes were offered for its development. In 1907 the Six Days' Trial took the form of a tour. In the same year, the Automobile Club of Great Britain and Ireland, by a special warrant from the King, became the Royal Automobile Club, and was fortunate in obtaining as its chairman H.S.H. Prince Francis of Teck, K.C.V.O., D.S.O., and the Auto Cycle Union was sufficiently lucky to secure his services as its president. No less than forty clubs became affiliated, and the total membership reached 2,231. In 1908 the Land's End to John-o'-Groat's run was held for the second time; fifty-eight entrants started and forty-eight reached John-o'-Groat's within maximum time; while in May the Annual Hill-climb was held at Sutton Bank, so as to give north-country riders a chance of competing. The Tourist Trophy Race was held in September, and the speed was limited as before by petrol consumption. Arrangements were made whereby members of the Auto Cycle Union could insure their machines at a very low premium. Several attempts were made to reduce toll charges in various parts of the country. The Touring and Legal Departments were also largely patronised by members. During this year the committee adopted a scheme for the establishment of local centres of the Union throughout the country.

Mr. A. George Reynolds, an energetic worker.

Military Motor Cyclists.

At the council meeting preceding the annual dinner it was proposed that the Union should form a scheme for placing a number of motor cyclists at the disposal of the nation in the event of a national danger, which ultimately resulted in the founding of the Auto Cycle Legion.

During the year which has just past, the A.C.U. continued its useful work, and when the Budget proposals were made public it was represented by Mr. Todd, who headed a deputation to the Chancellor of the Exchequer. The 1,000 Miles Trial was held, starting from a centre, Shrewsbury being chosen, from which daily runs were made into Wales and the country round Shrewsbury. The trial was of a very severe nature, but the machines entered behaved in a highly satisfactory manner.

The centre scheme prospered, and various centres were established and maintained in working order. The Tourist Trophy Race was held in the Isle of Man in September, and for the first time the petrol limit was abandoned and machines competed on cubical capacity alone.

On the occasion of the manœuvres the Army Council requested the Auto Cycle Legion to furnish a detachment of motor cyclists, who carried out their work so efficiently that a special letter of thanks was afterwards received from Sir Edward Ward.

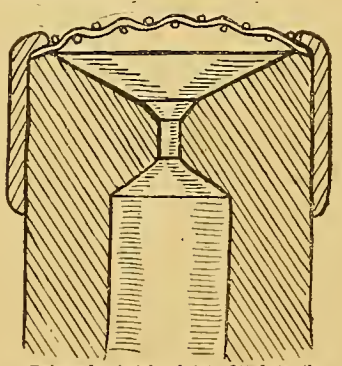
Who's Who in the A.C.U.

The photographs which are used to illustrate this article show a few of the moving spirits of the A.C.U., Prince Francis of Teck, the president, who is known all over the kingdom for the excellent way in which he has worked for the automobile movement; Mr. Robert Todd, the chairman, whose diplomacy has won for him an enviable reputation; Mr. Brooker, and Mr. Archibald Sharp, who are the backbone of the technical side of the Union's work; Mr. Reynolds, whose splendid powers of organisation have helped to make the Union the success it is; Mr. Cove, who works untiringly at competitions; Mr. Harding, who attends with great regularity all committee meetings; Mr. C. A. Smith, the hard-working and astute treasurer; and Mr. Straight, the indefatigable secretary.

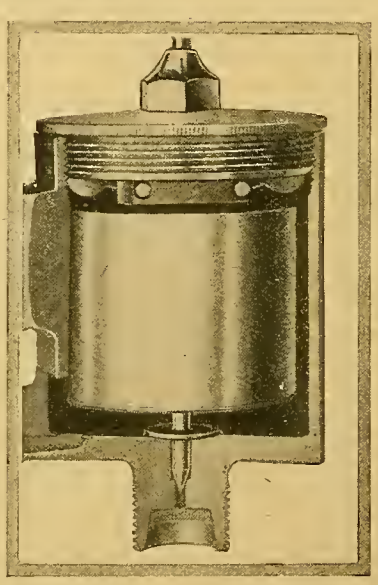
CARBURETTER ADJUSTMENTS SIMPLIFIED.

A VARIABLE PETROL LEVEL. UNIQUE DESIGN OF JET. THE USE OF GAUZES.

IT is generally known that the level of the petrol in the carburetter jet has an important bearing on the running of an engine. Successful competition riders know that a high level is necessary for fast hill-climbing and easy starting, whereas a low level reduces the consumption but renders starting more difficult. But varying the petrol level is easier said than done, and to the average motor cyclist it means a tedious and delicate operation. It is not every rider who knows that, within limits, varying the level of the petrol in the case of carburetters with toggle levers fixed inside the float chamber cover is the simplest operation imaginable. The Brown and Barlow, F.N., Triumph, and N.S.U. carburetters have the toggle levers and needle attached to the underside of the float chamber cover, and as the latter usually has a number of threads it will be obvious that by screwing the cover further into the chamber the lower will be the petrol level as the needle point is moved closer to the coned seating, and by leaving the cover partially unscrewed the level of the spirit is raised. This tip should be a lesson to novices to remember always to screw the cover well home after dismantling the carburetter, otherwise the former satisfactory level may be upset, with possible bad effects on the running of the engine. Naturally it is not prudent to overdo the screwing and unscrewing of the float chamber cover, as this method of altering the level is but a makeshift at its best, and if carried too far might result in the cover coming loose and being lost. A recently patented carburetter called the Condor possesses this feature of a variable petrol level by means of adjusting the float chamber cover. It is an improvement over the tip described above, as by the aid of an indicator and a graduated float chamber cap the operator is able to note the adjustment made, and, should it become upset from any cause, the readjustment is instantly effected. A stop is provided to prevent the cover coming adrift. It must be admitted that this arrangement will greatly simplify tuning up operations, as one has a guide to the particular level giving the best results for certain specified work, such as speed, hill-climbing, and low consumption. Moreover, think of the saving of time in arriving at the most satisfactory level, which in the ordinary course means many miles of experimenting. In the case of varying the level with the standard type of cap minus an indicator, one is working more or less in the dark.



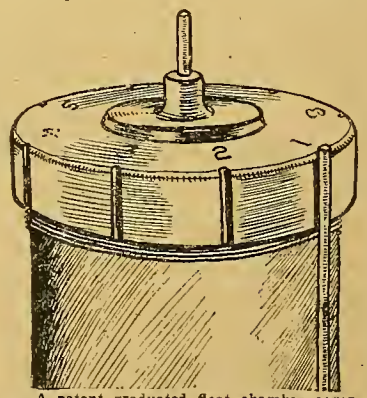
Enlarged sketch of jet fitted to the Condor carburetter. The special cup shaped end is to prevent flooding when a high level is used. Observe the gauze fitted immediately over the top of the jet. The advantages of this are mentioned in the article.



Section of a float chamber of standard type in which the toggle levers are affixed to the cover. By varying the depth to which the cover is screwed into the chamber, the petrol level may be altered.

A Special Cup-shaped Jet.

The Condor patent carburetter previously referred to possesses two other interesting features—one in connection with the special design of jet, and the other the wire gauze covering situated immediately over the jet to atomise the petrol effectively. These two parts are illustrated on this page. The unique design of jet is adopted to render possible considerable variation of the level by means of the graduated cover already referred to. As will be seen, the jet terminates in a cup or funnel-shaped formation at its spraying end. The wall of the cup projecting above the jet has the effect of preventing the petrol overflowing when a high level is used. The inventor of the Condor carburetter Mr. E. Sidwell, Coventry, asserts that he has proved that varying the petrol level at the jet gives precisely the same results as varying the jet area, this being assisted by the tapered formation of the jet.



A patent graduated float chamber cover and indicator. This is a reliable guide for varying the level of the petrol in the jet, and the simplest possible means of effecting what is usually a delicate adjustment.

Some Advantages of a Gauze over the Jet.

The gauze covering for the jet would probably result in a general improvement in running if fitted to existing carburetters. It is common knowledge that some carburetters do not effectively atomise the petrol, but pass a column of spirit in a more or less compact mass until it reaches the engine. The wire gauze is provided to atomise the petrol effectively, which results in more economical running. Gauzes have been frequently used in induction pipes, and many contend that no difference in the running is noticeable with a single gauze fitted or not. Two reasons have been ascribed for this contention. Firstly, the

Carburetter Adjustment Simplified.—

gauze was placed at such a distance from the jet that the velocity of the fuel had fallen to low values; secondly, air impregnated with road dust, etc., was drawn through the gauze at the same time, the latter making an effective trap for most of the dust and foreign matter, with the result that the supply of mixture was quickly choked. In the case of the Condor carburetter the gauze cap is placed immediately over the jet, and through which only petrol passes. By this arrangement it is claimed that a finely sprayed mixture is obtained, such as would be given by a large number of tiny jets, but without the tendency these latter have of becoming choked with foreign matter. The gauze cap is readily detachable, being pressed on to the jet tube and held securely in position by the pressure of its own spring sides.

The advent of a properly graduated float chamber cover to vary the level of the spirit marks another definite improvement in carburetters, for in combination with an adjustable main air intake such as we have illustrated and dilated upon from time to time an experienced motor cyclist with a knowledge of the principles of carburation would have complete control over the vital adjustments of the carburetter *from the outside*, and would be able to make a well-tuned engine far more flexible than is possible with any fixed proportions of main air and petrol.

THE PROBLEM OF THE PRIVATE OWNER.

Summary of a Paper read before the members of the Auto Cycle Union by the Rev. P. W. Bischoff.

ON Thursday last, the 13th inst., at 112, Piccadilly, the Rev. P. W. Bischoff introduced the problem of the private owner of a motor cycle in his paper read to the members of the A.C.U. Below we give a summary:

The subject of this paper is by no means confined to motor cyclists, but is a feature in the conduct of every sport in which amateurs and professionals engage in friendly rivalry. There is nothing in the problem unpleasant or unnatural: it is the legitimate offspring of enthusiasm and emulation. The governing body of every sport has had to face it and deal with it in a way conducive to the encouragement and purity of the sport.

Hitherto, however, the question has been left severely alone, perhaps because no one has been found of sufficient temerity to bring it forward. But I cannot see why there should be anything invidious in this distinction between the amateur and the professional. In fact, I cannot allow that any aspersion is cast on anyone, be he amateur or professional, by dwelling on this distinction between them, but rather the reverse. In short, my great desire is to put aside all question of personal conflict, and to regard the subject in the light of what it really is—one of the vital factors in the problem of pure sport.

A Survey of Other Sports.

What is this distinction between the amateur and the professional, and why should there be one? The reply is best met by a survey of the situation in other sports. In all these there are found taking part those who do so for sheer recreation and those who do so as a commercial undertaking, or, rather, on the strict etymology of the two words, the amateur who does it for the "love" of the thing and the professional who "publicly avows" that it is his livelihood.

When they compete against each other, two facts become manifest—one that between the experts (the men in the first flight of each class) there is practically nothing to choose, though the professional shows a slight superiority; the other that amongst the rank and file this superiority of the professional is quite pronounced. This is perfectly natural, and not at all surprising: there is nothing in it derogatory to the amateur or suggestive of sharp practice on the part of the professional. It follows as a matter of course that the man who spends his whole time on any particular occupation, trained up to it by a tedious apprenticeship, and kept up to it by the incentive of modern competition, will be better at his own job than one who takes it up comparatively late in life as a means of pleasantly occupying his spare moments.

But—and here comes the crux of the whole matter—the man in the trade may give his whole heart to the production and perfection of his goods, but it will be in vain unless he can command a big lay market. This leads us to the obvious deduction, so often overlooked, that each class is the complement of the other. If they pull together each gets what he wants: if they rub each other the wrong way both equally will suffer for it. So the professional cannot afford to crush the life and aspirations out of the amateur by getting all the plums, or he will find his market gone: nor can the amateur afford to snub and depreciate the professional, or he will discover that his sport is at a standstill or on the down grade.

To Safeguard the Interests of the Amateur.

Therefore we have a governing body for each sport. The object of these bodies is not to impose certain arbitrary restrictions on the conduct of competitions and to rake in the resultant fees. Their true aim is to foster and encourage sport. With this intent they certainly do promote meetings and consequently issue rules for their conduct, and, of course, require the necessary lubrication to keep their machinery in running order. But a prolonged investigation of the policies of all such bodies of which I have been able to obtain any information has pointed out to me one salient feature—that their prime object has invariably led them to safeguard the interests of the amateur. Now please notice this expression, as it is of paramount importance in the investigation which we have in hand. I do not say to coddle or bolster up the amateur and persuade him into thinking that he is a very fine fellow, but to "safeguard his interests," to enable him to win competitions on his merits, and by his abilities to create for himself an honourable position in the eyes of his fellow men. This is at once a confirmation and an illustration of my contention, which no one can seriously dispute—that the amateur and the professional are the complement of each other, and that, if either suffers, both the trade and the sport will inevitably decline.

A reference to the discussion which followed the above interesting lecture will be found in the four-page supplement included with this issue.

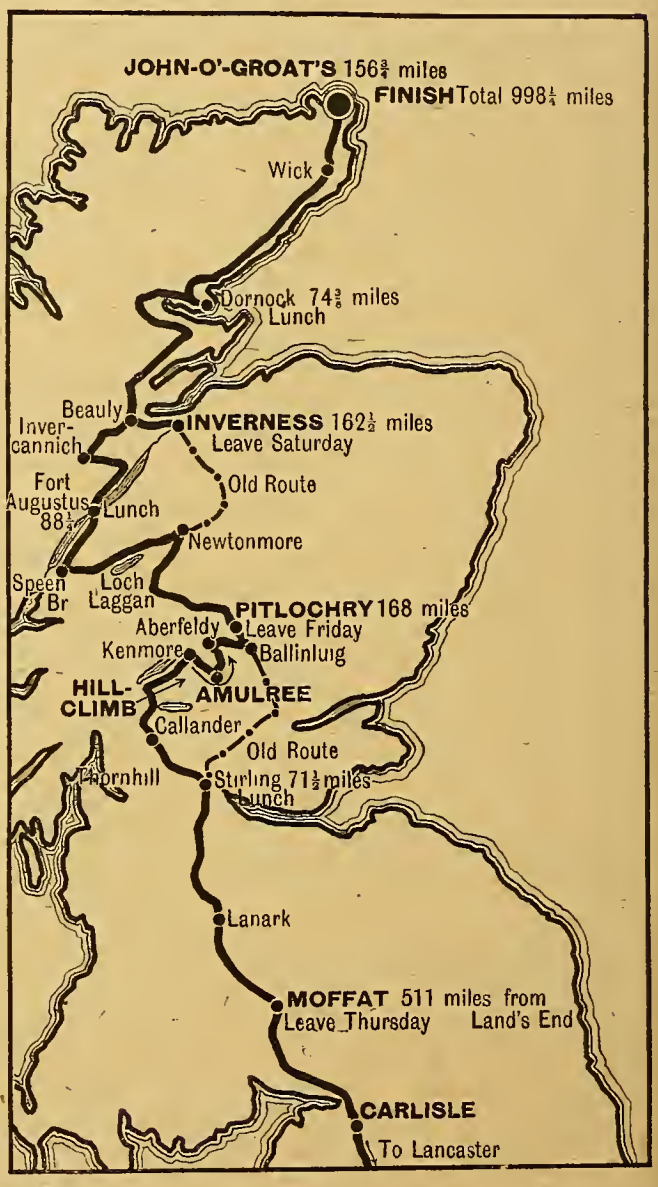
A SIMPLE PETROL FILTER.

The subject of the annexed illustration is a simple form of petrol filter, which is screwed into the petrol tap bush under the tank by the thread A. The filter consists of a pipe B, lined with fine copper wire gauzes C, and is provided with two long slits running nearly the whole length of the pipe. The petrol is free to flow through these slits, but any foreign matter which would be likely to choke the jet is arrested by the gauze, and as the pipe stands upright in the tank, it is kept clean by the wash of the petrol. The nut D is threaded internally to take the petrol tap and union combined, to which the petrol pipe is attached for feeding the carburetter. It has been protected by a motor cyclist named Conrad New, and is being marketed by J. and R. Oldfield, Refulgent Lamp Works, Warwick Street, Birmingham.

Land's End to John-o'-Groat's Trial, 1910.

THE idea of extending the route to bring the competitors back either to Edinburgh or to some other point on the homeward journey has been abandoned, as this would have resulted merely in unduly lengthening the course without making it any more severe. Instead, the route has been altered so as to include the Kenmore side of Amulree Hill and to bring the competitors into the finest scenery the Highlands can afford. The journey will be continued as before to Moffat, the competitors leaving here on the Thursday morning. Lunch will be at Stirling, as before, and thence a new route will be followed through Thornhill, Callander, along the shores of Loch Tay to Loch Tayhead, where the men will turn to the right and ascend the steepest side of the famous Amulree Hill—a climb which will certainly thin out the weaklings and call for the greatest skill on the part of the riders. The route then passes by the Amulree Hotel, and continues along the better known road to Aberfeldy, and thence to Ballinluig and on to Pitlochry, where Thursday night will be spent. Leaving Pitlochry on the Friday morning, the route extends over the Drummochter Pass to Newtonmore, where it turns sharp left and proceeds along the shores of Loch Laggan to Spean Bridge, where a turn to the right is made. At this point there is a magnificent view of Ben Nevis. The route continues along the banks of Loch Oich to Fort Augustus, where probably lunch will await the competitors. After a detour in the Western Highlands Beauly will be reached, and finally Inverness, where the Friday night will be spent. The competitors will find Inverness a far more pleasant place to stop in than Tain. On the Saturday the usual route to John-o'-Groat's house will be followed, except that lunch will be provided at Dornoch. This alteration of the route, which not only makes the trial much more severe, avoids stopping at one town where the accommodation has not been all that has been desired, and embraces some of the finest Scotch mountain scenery, should prove to be a great attraction, while, in addition, it brings the mileage approximately to 1,000.

The accompanying map shows the amended route which the competitors will follow in Scotland, the dotted portions indicating the old course in 1908.



THE MOTOR CYCLING CLUB ANNUAL GENERAL MEETING.

THE Motor Cycling Club annual general meeting was held at the Inns of Court Hotel, at 8 p.m., on Wednesday last, under the able chairmanship of the club's president, Mr. Charles Jarrott. Some thirty-one members were present.

The first business on the agenda was the election of officers. Mr. Jarrott was re-elected president amid acclamations, while the following were re-elected vice-presidents: Messrs. A. Brown, S. F. Edge, J. van Hooydonk, E. Perman, S. J. Sewell, and J. A. Jackson; captain, Mr. E. B. Dickson; hon. sec., Mr. A. Candler; hon. treas., Mr. R. C. Davis.

Mr. R. C. Davis then proposed several alterations in the club's rules, which dealt principally with the following points, and were finally adopted: (1.) That candidates for membership should pay their fees in advance. (2.) That any member of not less than ten years' standing may become a life member on payment of five guineas; or that any member who has served the club signally may be made an honorary life member without payment of fee. (3.) That a member, if his conduct shall justify it, may be compelled to resign if in the opinion of the committee or of any twenty members his conduct shall be injurious to the character or interests of the club. (4.) The abolition of voting by proxy.

During the election of the executive committee, for which Messrs. S. J. Sewell and A. F. Ilsley acted as scrutineers, the secretary asked the meeting for views on the club's programme, and especially the trial for the Jarrott Cup, which it was proposed to run off at Easter. Mr. Karslake suggested another twenty-four hours run, and did not fully agree with holding the twenty-four hours run, London to Land's End and back, at Easter. Mr. Head then explained that it was necessary to hold this competition during the Easter holiday, as late in the year the men went through so many trials of a similar nature that they lost interest to some extent. Mr. Boileau reminded the meeting that Easter would fall a good deal earlier this year than usual, and if wet and cold were experienced they were a combination not particularly desired on a twenty-four hours run.

The election of the 1910 committee was then announced. It consists of Messrs. R. H. Head, S. H. Fry, E. Gwynne, J. van Hooydonk, C. J. Seed, C. Gibbons, F. J. Jenkins, L. A. Baddeley, H. G. Bell, T. Pears, W. H. Wells, and L. Vedy.

BORE-STROKE RATIO & EFFICIENCY.

A REPLY TO JAMES L. NORTON.

By A. A. SCOTT.

IN replying to the contention that an increase of stroke without an increase of capacity gives greater power per revolution, it is necessary first of all to agree as to the limits of long and short stroke ratios. Taking the figures given in *The Motor Cycle* Buyers' Guide for February 17th, 1909, it will be found that the mean dimensions of 160 different single and twin-cylinder motor bicycles are as follows: Average bore, 74.743 mm. = 2.94in.; average stroke, 91.269 mm. = 3.19in. Hence the stroke of the average motor bicycle engine is very nearly 1.1 times the bore, consequently we can classify engines as *short* or *long* stroke, according to their variation from this proportion. An engine 3in. × 3in. should be therefore regarded as a short stroke engine, although of equal bore and stroke. This is a favourite proportion, and taking this as a standard type it can be definitely stated that if while retaining the same capacity we either lengthen or shorten the stroke, we shall not gain any increase in power per revolution, although we may find less overheating with the longer stroke, and a higher speed attainable with the shorter stroke.

Extreme Comparisons.

As I have pointed out above, the normal engine has a stroke 1.1 times the bore, therefore, in my opinion, the extreme comparison selected by Mr. Norton for illustration is only useful to point out the disadvantages of extremes, and as such abnormally short stroke engines are not in common use, it is better for the purposes of a fair comparison to consider ordinary types used in daily practice on the road.

For a practical illustration I prefer to consider the distinctive features of two engines having a similar capacity of approximately 12½ cubic inches—a long stroke 2in. × 4in. and a short stroke 2¾in. × 2⅛in. The dimensions are given in inches for the simple reason that in our investigation it is preferable to give the cylinder pressures in lbs. per square inch rather than in grammes per square centimetre, and also because of the greater simplicity of the figures we require to use.

Before proceeding to note the peculiarities of each engine, it will assist us in our investigation to understand exactly what happens in the cylinder of either engine. Now there appears to be a general impression among both riders and makers that the cylinder compression reaches 100 lbs. per square inch.

Actual Compressions.

The results from actual diagrams obtained by the use of a high speed indicator from several of the latest makes of air-cooled motor cycle engines show a maximum cylinder compression of 55 lbs. per square inch, and 60 to 65 lbs. per square inch in high compression T.T. models. The practice of attempting to gauge the compression by fixing an ordinary dial recording pressure gauge—or other similar device—to the sparking plug hole has probably led to this exaggeration, for in this case the reading is entirely unreliable since the pressure shown on the dial depends largely on the speed of the engine and the inertia of the needle hand.

Mr. Norton assumes a pressure of 73.5 lbs. isothermal, and goes on to say that the absolute pressure would be higher—probably over 100 lbs.

In the first place, the expression "absolute pressure" should be confined to its proper use—to define pressures, including the pressure of the atmosphere, as opposed to gauge pressure. Secondly, isothermal compression does not take place in the cycle of an ordinary motor bicycle engine, and could only be obtained by maintaining an equal temperature throughout the stroke, by injection of water, etc., as in air compressers. As a matter of fact, the compression, as well as the expansion curves, show a very near approach to the adiabatic, and without going fully into this very interesting subject, it is enough to state that while the well known expression $PV^{1.41}$ = constant, holds good for the compression of air, different results are obtained from the compression of carburetted mixtures, and from the expansion of their products of combustion, so that a partial adiabatic curve is shown on the diagram (see fig. 1). This leads to the curious fact that when the engine is drawing in pure air only there is actually a higher cylinder compression than when inducing its usual mixture from the carburetter, assuming, of course, that the charges are not ignited, so that the temperatures are on an equal basis.

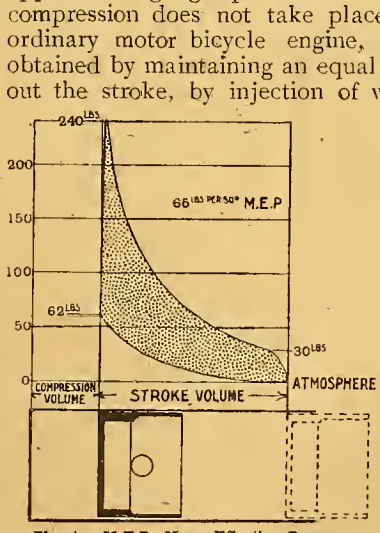


Fig. 1.—M.E.P. Mean Effective Pressure.

Now an engine is never the perfect machine it is assumed to be theoretically, and if we wish to arrive

Bore-stroke Ratio and Efficiency.—

at a practical working index of compression, we must analyse the curves shown by these indicator diagrams and find out exactly what happens under working conditions.

The writer has found that by taking the mean result from actual working diagrams obtained from different types of small petrol motors, the index for the compression curve is 1.26, and 1.36 for the expansion of the products.

Applying this to Mr. Norton's sample engine having a compression space equalling 25% of the piston displacement, we have $\frac{\text{Total volume}}{\text{Compression space}} = 5$, and since $PV^{1.26} = P_1V_1^{1.26}$, the ultimate pressure P_1 is easily found as follows:

$$P_1 = P\left(\frac{V}{V_1}\right)^{1.26}$$

$$\log P_1 = \log P + 1.26 \log (5)$$

Hence P_1 = 112 lbs. absolute or 98.3 lbs. per sq. in.

It has already been shown that such high compression is not found in air-cooled engines, and seldom in water-cooled engines, so that we can more fairly base our calculations upon a maximum compression of 62 lbs. per sq. in., and for this a combustion space of $\frac{1}{8\cdot66}$ the total volume is required.

Loss of Heat Confined to Combustion Chamber

Fig. 1 shows graphically the gradual increase of pressure during the compression stroke, the almost instantaneous rise resulting from explosion, and the rapid fall during the beginning of the expansion stroke, and it will be seen at a glance that an extreme pressure (with corresponding temperature) occurs almost momentarily at the beginning of the power stroke; the fall of pressure being so rapid that only the internal surfaces of the combustion chamber are exposed to this extreme temperature, consequently, since by far the most serious loss of heat occurs at this period, we can, for the purpose of comparison, confine our account of the loss of heat through the cylinder walls to the surfaces of the combustion chamber, although heat is still being lost in a minor degree throughout the expansion stroke.

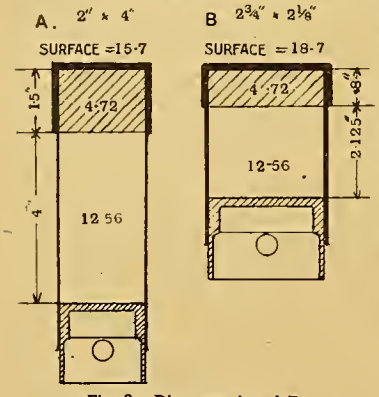

Fig. 2.—Diagrams A and B.

The diagrams A and B (fig. 2) show side by side the types of cylinder selected for comparison. The volumes are equal. The shaded areas represent the compression spaces, and the pistons are shown at the bottom of the stroke.

The short stroke B has three square inches more surface exposed to the explosion temperature than A, so it must be admitted that, comparatively, the short stroke exposes more combustion surface than the long stroke engine.

Now the comparative effect of this extra three square inches of surface will be to make the expansion curve fall more rapidly, causing the area of the diagram to be reduced, so that here we have a definite loss of power in the short stroke engine, and the obvious way to compensate for the extra surface exposed is to reduce the time of exposure by the higher rate of revolutions attainable with the shorter stroke. The effect of this higher rate of revolutions on the induction stroke we shall consider later.

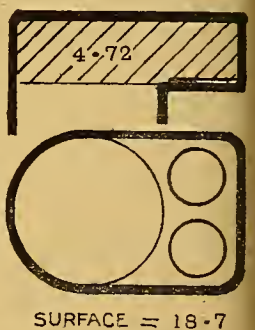

Fig. 3.—Diagram C.

Assuming equal revolutions per minute, does this extra surface cause an appreciable loss of power in the short stroke? In diagrams A and B the combustion chambers are entirely circular, without valve chests, so that the necessary valves would require to be placed in the head, opening directly into the combustion space. Now if we make the combustion chamber of the long stroke engine in the ordinary way with the usual valve chest (see fig. 3), a practice adopted on the most successful and efficient motor cycle engines of to-day, we shall lose the advantage of less surface, for although the volume remains the same, the surface exposed to the explosion temperature will now be increased by three square inches, and consequently the overhead valve short stroke engine will be as thermally efficient as the ordinary build of long stroke engine. The question therefore arises—If this extra surface has any appreciable effect on the power of high speed motor cycle engines, how is it that the standard side valve chest type of engine is so efficient compared with the overhead valve type?

It will be admitted that the same advantage is gained by adopting the overhead valve type, as by increasing the stroke ratio, and in this connection it might be observed that the valveless, two-stroke engine has this advantage without the mechanical objections of overhead valves.

Our investigation of the long and short stroke types has so far led us to agree with Mr. J. L. Norton that the short stroke shows comparatively greater area exposed to the hot gases, but on turning to the comparison of mechanical efficiency we shall find a counterbalancing effect in favour of the short stroke.

Fortunately, it is admitted that friction is independent of surface, and is in proportion to the load, so that we have no difficulty on this point in proving that the short stroke engine shows an appreciable gain in mechanical efficiency.

Frictional Loss Caused by Piston Rings.

Alhough Mr. Norton gives figures to show the increased load on the bearings of the short stroke engine, the most serious frictional loss in the engine is passed over. Now it has been proved by experiments conducted by some of the well-known makers of high speed steam engines that the friction of the bearings is quite negligible compared with the friction caused in a high speed engine by the piston rings, and although the rings of the short stroke engine are larger

Bore-stroke Ratio and Efficiency—

in diameter, we are agreed that the extra surface of this larger ring has no effect in causing friction. It is obvious, therefore, that the pressure of the ring against the walls of the cylinder will not be much greater, and could be made the same as in the smaller diameter, but on turning to fig. 2, diagrams A and B, it will be seen that the piston of the long stroke A has to travel nearly twice as far as B, so that for one power impulse we find that the piston of A travels 16in., while the short stroke B travels only 8½in., so that the long stroke type has the extra friction of moving its piston rings through a further distance of 7½in.

That is to say, for the same power impulse the long stroke engine has to develop an extra amount of power to compensate for a frictional resistance equivalent to nearly four strokes of the short stroke piston.

There is also the friction of the piston against the cylinder wall, but if long connecting rods are fitted this is scarcely worth taking into account, compared with the severe frictional losses caused by the rapid motion of the piston rings. Here we have a distinct gain in mechanical efficiency to set off against any thermal loss. As for the extra load on the short stroke piston, this can be met by proportionately designed bearings, and since in the case of motor cycle engines ball bearings are commonly used, no important frictional loss need occur from this cause.

Load on Bearings Momentarily Applied.

It can also be shown that the extra load is only momentarily applied to the main bearings at the dead centre, and that when the piston is in mid position the load on the main bearings of the long stroke engine is increased by the leverage of the longer crank, since we are assuming the same rate of revolutions, and consequently the same gearing.

For instance, from our indicated diagram we find that with the piston in mid position the M.E.P. is about 60 lbs. per square inch, so that the load on the piston of A = 188 lbs.; B = 355 lbs.

Assuming a belt pulley with pitch circle = 4in. diameter, the load on the main bearings of A will be twice that on the piston = 376 lbs., but, owing to the effect of the shorter crank of B, the load on the main bearings is only approximately 1½ times the piston load, so that instead of 710 lbs. we have the reduced load of 530 lbs. on these bearings, while in both cases the pull on the belt is the same—approximately 188 lbs. (see fig. 4).

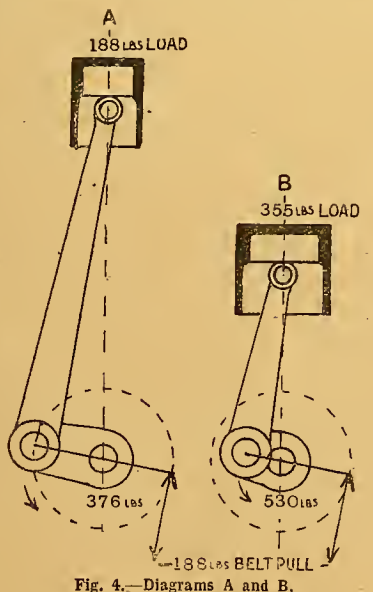

Fig. 4.—Diagrams A and B.

We have yet to consider the effect of high speed, for by an increased rate of revolutions the period during which the extra surface of the short stroke is exposed to the gases can be reduced, so that its thermal efficiency is equal to the long stroke. Since the revolutions per minute are limited by the piston speed, the short stroke B can be run at a greater number of revolutions than the long stroke A.

The Effect of the Inertia of Reciprocating Parts.

Another practical limit to high speed is the effect of the inertia of the reciprocating parts. Now a large diameter piston can be made lighter in proportion to its size than a small diameter piston, and if the correct length of connecting rod (2.5 times the stroke) be used in both types, the long stroke will have a heavy rod with 10in. centres, while the short stroke will have a rod which, owing to its shorter length of 5.3in. centres, can be made less than half the weight.

For comparison it can therefore be fairly assumed that the piston of A = 1 lb. and rod = 1½ lbs., while piston of B = 2 lbs. and rod ¾ lbs., so that the reciprocating mass of A = 2½ lbs. and that of B = 2¾ lbs.

Now it is easily found that at 2,000 revolutions per minute the resistance to retardation at the top of the stroke of A = 679.2 lbs.; B = 398.4 lbs.

Hence B must make 2,610 revolutions per minute to show equal inertia, so that we find a direct contradiction to Mr. Norton's statement that there is a considerably higher limit of safe piston speed in the long than in the short stroke. We have given the same proportion of connecting rod length in both cases, but in order to reduce the excessive overall dimensions of the long stroke a short rod is generally used. If then a rod only twice the stroke be used, the inertia of A (at top of stroke) = 707.7 lbs.

Now the shorter the rod the greater the pressure thrown on the cylinder wall during the power stroke, and, since it is decided that friction is in proportion to the pressure, this means additional frictional losses in the long stroke engine.

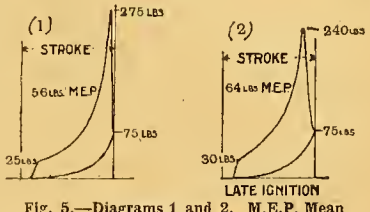

Fig. 5.—Diagrams 1 and 2. M.E.P. Mean Effective Pressure.

In some designs the crankshaft is off-set, in order to reduce the angularity of the rod on the power stroke, and since this arrangement requires extra clearance for the rod, it is more practicable on short stroke engines owing to increased diameter of the piston.

The Speed of the Gases.

When we come to consider the effect of speed on the four strokes of the Otto cycle, we shall, no doubt, at first glance be intimidated by the symptoms so graphically described by Mr. Norton. If during the one-fifty-fourth part of a second we have vacuums aching for a full charge, with hesitating inlets, etc., imagine the profound distress of the gases in a two-stroke engine where they have to hustle about the same business in one-hundredth part of a second!

Imagination is not a reliable guide for a correct estimation of the behaviour and speed of gases, and, provided the valves of the engine are large enough to permit of a mean speed of 80ft. per second, there ought to be no complaints on the part of either the incoming charge or exhaust. What actually can be

Bore-stroke Ratio and Efficiency.—

done in this direction with properly proportioned areas of discharge is shown in fig. 5, diagrams 1 and 2.

These are actual indicator diagrams taken from a 4in. × 4in. two-stroke water-cooled engine at 900 revolutions per minute, and the almost vertical drop from 30 lbs. pressure to the atmospheric line shows convincingly that here at least there is no hesitation on the part of the exhaust in getting out of doors.

Now the inertia of the exhaust gases must be greater than the inertia of the fresh charge, owing to their greater weight, so if we can detect no trace of hesitation, or rebounds, etc., in this summary eviction of the exhaust, we are not justified in suspecting the incoming gases of irregular behaviour in the seclusion of the inlet pipe. So in considering the effect of high speed on the power stroke we cannot take it for granted that the compression is lowered to any appreciable extent.

However, even if the effect of this higher rate of revolutions is to cause a slower ignition of the charge, accompanied by after burning, it does not follow that there is any actual loss of power, since diagram 2, in which these symptoms occur, shows an actually higher mean effective pressure than diagram 1, where the ignition is almost instantaneous.

High Speed and Valve Timing.

The general effect of high speed on the valve timing is, no doubt, to reduce the efficiency, but in these days of piston valves, rotary valves, sliding sleeves, and last, but not least, two-stroke engines, this becomes less felt, and can be minimised by good design.

We can therefore fairly allow the short stroke the advantage of a proportionally higher speed, and if we view the matter from the practical standpoint of power in relation to weight, as well as efficiency, the verdict must be in favour of the short stroke engine.

Adopting Mr. Norton's definition of flexibility, as representing the difference between the maximum and minimum number of strokes per minute, we have already found that, assuming that mechanical losses of A compensate for the thermal losses of B, the short stroke is more flexible, since it has a greater range of effective strokes.

It cannot therefore be held that the long stroke will do more real work with a lower gear, or that it accelerates more rapidly.

My contention is that the short stroke gives: (1) Equal efficiency and equal power per cubic inch capacity. (2) Greater range of speed. (3) Less vibration at equal speeds. (4) Less weight per horse-power. (5) Greater convenience for motor-cycle design.

The seven conditions affecting thermal efficiency given by Mr. Norton in his letter of January 3rd are all to a limited extent agreed upon in the foregoing, but we have shown that the practical effect of this thermal loss on the power of the engine cannot be considerable in view of the undoubted efficiency of the standard valve chest type of engine.

The assumption that valve dimensions are proportionate to piston area can easily be proved to be wrong by referring to the speed of the gases. Since at equal revolutions per minute we require to draw into the cylinder the same volume of fresh charge, or to expel the same amount of exhaust gases, it is evident that the valve areas must be proportionate to the piston displacements, and, as these are equal, the valves are also of equal size.

Having shown that equal volumes are induced and discharged through equal valve areas, the speed of the gases must be the same in both types, and consequently both engines will be subjected in the same degree to the throttling effect caused by high speed.

The short stroke is particularly adapted for the construction of a motor bicycle with the engine weight low down, but with the usual vertical type of engine the increased height of the long stroke cylinder gives a raised centre of gravity, while it has not been proved that it compensates for this disadvantage by increased efficiency, flexibility, and economy.

WATER-COOLING ON MOTOR BICYCLE ENGINES.

APROPOS the discussion on water-cooled engines for motor bicycles, it is interesting to read two well-known aviators' opinions with regard to air *v.* water-cooled engines. Of course the conditions on a motor bicycle and aeroplane are somewhat different, but the same object is borne in mind by designers, viz., utmost power and efficiency for weight carried.

Mr. Wilbur Wright in the course of an interview said he did not believe in air-cooled engines. He had used them on the engine of his aeroplane, but afterwards replaced the cylinders with water-cooled ones, as he found that with continuous running there was a tendency so to heat the motor that what might be saved in weight by not having the water and a radiator was more than compensated by the fact that the motor did not give as much power. His brother's experience was the same.

Glenn H. Curtiss, who, as we have already stated in these columns, is not only one of the leading aviators, but a motor cycle manufacturer also, is said to be a strenuous advocate of air-cooled motors, but it is worthy of notice that he is supplying his commercial aeroplanes with water-cooled motors, and also used a water-cooled engine of racing type when making his record flights at Rheims.

However, the leading French aero engines, including the seven-cylinder rotary Gnome, Anzani, Renault, etc., are air-cooled, so that opinions are divided in the aero world as well as among motor cyclists.

The 1910 catalogue of Rex motor cycles is to hand. It contains descriptions of the various models and engines, illustrated by photographs and drawings. It is interesting to note that purchasers of these machines have the option of the Rex valveless two-stroke engine to any model without extra charge. Parts such as the patent automatic lubricator for engine, plate clutch hub, and two-speed gear and clutch made under Roc patents have been specially illustrated and described. For 1910 the Continental rubber non-skid tyres have been adopted as standard, 2¼in. tyres being fitted to the Tourist machines and 2½in. to the de Luxe models. The catalogue can be obtained from the Rex Motor Mfg. Co., Ltd., Coventry.

TRICYCLES FOR ALL-WEATHER RIDING.

I SHOULD like to add my experience and views to the others which have been appearing on the highly interesting topic of tricycles. The two illustrations are of a tricycle I put together last March, and during the intervening period I have covered 6,304 miles, including twenty-five runs exceeding 100 miles, some of them being over 200 miles. The districts traversed were East Anglia, South Coast, London and district, Devonshire, South Wales, etc., under all conditions of weather, and sometimes pulling a trailer with 8 and 10 stone passengers.

Specification of the Tricycle.

As regards the specification of machine, it has a 1908 Quadrant a.o.i.v. engine set, cylinder 81 × 88 mm. bore and stroke, Bosch magneto (situated at the rear of the cylinder), Longuemare carburetter, Chater-Lea frame with Millford forecar attachment but minus the chair. I removed the pedalling gear, and fitted long footboards in its stead. There is a luggage carrier provided over the front axle. Other extra fittings are a Mabon clutch, Cowey speedometer and milometer, XL-All spring seat-pillar, handle-bar mirror (a valuable accessory), 26in. × 2in. Clincher A Won front tyres, 26in. × 2¼in. Clincher A Won back tyre, Stanley Dermatine ⅞in. belt. There is only one brake—a Chater Lea band brake—on back wheel.

Its Performances.

The machine has proved most reliable, and a fine hill-climber, but for hilly country a two-speed gear would be a great advantage. I use a gear of 4¾ to 1, and it easily takes me up Star Hill, Sevenoaks, and hardly troubles about Riverhill. The machine has touched 45 m.p.h. on Brooklands Track, and will do 40 m.p.h. on any good road. It is very easy to steer, corners may be taken at high speed and with perfect safety if the rider leans well over on the inside, but it is not advisable to exceed 12 to 15 m.p.h. round a right angle corner. My machine has always been easy to start. In regard to brakes, the one fitted will lock the wheel on any gradient, but never stops the machine with a shock like some push-bicycle brakes. I consider that front wheel brakes are a disadvantage on a three-wheeler such as mine, as they put a strain on the frame, and are almost impossible to keep properly adjusted.

Cost of Running.

One tank full of petrol (about 1⅓ gallons) will last for about 100 miles. The tyres referred to will stand about 7,000 miles wear on front wheels and 2,500 on back. Belts are good for well over 2,000. My record for a Stanley-Dermatine belt, purchased in two pieces (a cheap line) at 8s., is 2,804 miles, while a well-known foreign make which cost 15s. wore out in 658 miles when the machine was in use as a bicycle.

The Virtues of a Powerful Lamp.

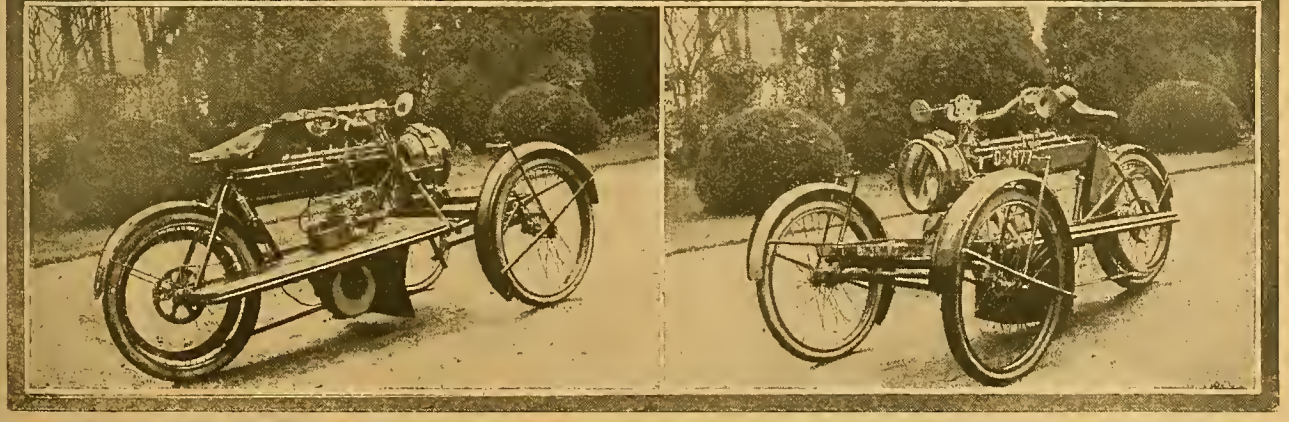
I purposely omitted any reference to the lamp in the specification, as I wanted to make special mention of this important accessory. This was the one, I believe, referred to in *The Motor Cycle* under "Current Chat" of November 8th. The paragraph was headed "Over-doing It." Well, I don't agree. This large car lamp has proved invaluable on long journeys in strange parts, as it lights up objects a long way ahead, not only in the centre of the road but the whole width, including the houses on either side. Another point in its favour is that one is enabled to read finger posts while going slowly past, instead of having to stop and direct the beam on to the post, which is the only thing to do with the usual motor cycle lamp. The make I use is a Willocq-Bottin, with oval plain glass and burnished metal interior. The generator is an ordinary drip feed. The heavy lamp necessitated a strong support, so I had a special bracket made by the Valiant Works, Riverhead, Sevenoaks, and it keeps the lamp rigid.

In conclusion, I can with confidence urge any reader who does not care to risk a side-slip by riding a motor bicycle in mud, tramlines, and grease, to try this type of combination. Of course, having three tracks it gives one a shaking on bad roads; neither is it so fast as a motor bicycle, but it is surely more sensible to use a tricycle than lay up a bicycle for the winter.

No mud or grease will make it side-slip more than a few inches, but it is advisable to switch off the engine when the back wheel is crossing wet tramlines, as it will shoot off very suddenly, and should it strike any object raised above the surface of the road it might cause the machine to overturn.

The slight discomfort on bad roads may be overcome very largely by having the front axle sprung.

RAYMOND V. E. DE B. CRAWSHAY.



Threequarter views of Mr. Raymond V. E. de B. Crawshay's tricycle, his experiences with which are published above.

OCCASIONAL COMMENTS.

By "IXION."

The Future of the Tricycle.

I see I managed to tread heavily upon sundry toes when I wrote my notes on the future of the motor tricycle as a solo mount. I am neither surprised nor annoyed about that; no publicist can altogether avoid occasional mishaps of that kind. But I plead guilty to feeling a certain impatience when the owner of the crushed toes talks as if I dared to speak without experience. I can claim some years' experience of the solo motor tricycle, implying as big a mileage as most three-wheel enthusiasts, and my mature opinion is that if there is a sound solo three-wheeler on the road it is one of the 1910 patterns, which I have yet to sample. Facts are surely on my side.

Ever since the motor bicycle was invented two drawbacks have scared would-be votaries: one is its liability to skid, the other is the fact that a stoppage necessitates a dismount, and in winter a dismount into mud. Dozens of designers and inventors have attempted to evade these inherent defects of the two-wheeler by producing tricycles of all sizes and sorts and shapes; but the great mass of motor cyclists remain faithful to the two-wheeler or prefer dropping their hobby in winter. *Ergo*, poor old much-maligned "Ixion" is not a purblind, prejudiced juggins when he doubts whether the solo tricycle possesses a brilliant future.

The Twisted Leather Belt.

Something of the same despair possesses me when I read my critics on the subject of the twisted round leather belt as a motor cycle transmission. Of all motor cycle transmissions it was the first. It remains the cheapest and the simplest to adjust. Yet only two or three makes of machines retain it, and they stand alone in a special class. Yet when I meekly venture to suggest that these facts prove it to embody certain inherent drawbacks, rendering an alternative transmission desirable, it takes an unlimited vocabulary to paint my character in its true colours.

Reforms in Big Trials.

While the silly season lasts, will some kind friend think out a sound plan of checking riders' times in an entry of sixty competitors or so, and present it to the A.C.U.? Friends who have a big experience of long trials tell me that the anxiety of getting their checks right quite spoils the fun.

To start with, even if there are no secret checks dimly shadowed forth in the rules, there is at any rate the bother of carrying two watches (in case one stops, as it often will on a motor cycle), and of keeping these two watches synchronised with the official turnip.

Having successfully surmounted these initial difficulties, you have next to find your way—easier in an A.C.U. trial than at any other time, but not always easy even then. You have then to keep your motor running and climbing—easiest with a [No free advertisements, please!—ED.]. Finally, conqueror of these colossal obstacles, you arrive at some measly little one-horse village or market town. The schedule allows you one hour for the next twenty miles after being timed through this check, and you are punctual here. But ere you can proceed you have to get a fill of petrol and sign the checking sheet. You attempt to sign the checking sheet. A youth, who has been doing nothing all day, and is rather conceited because he has a bit of coloured ribbon in his buttonhole, is muddling things finely, and as forty or fifty men are all trying to sign the sheet in due order, he is getting raggy, and making more and more of a muddle. There is ten minutes margin between minimum and maximum time, and, thanks to the inexperience of the checker and the crowd he has to deal with, this is all gone before you get a chance to sign. He books you as outside maximum time, but a judge arrives, you explain, and he antedates your signature. Thank goodness.

You now have twenty miles to do in sixty minutes. Nice time for a smoke and a look round, you think. Not a bit of it. You need some more petrol. You join an infuriated mob round a small ironmonger's shop. Fifty riders are struggling for one funnel, the supply of petrol is all but exhausted, and finally when you get away you have just got threequarters of an hour to do the distance in. This scene is repeated at intervals all day long. Sometimes the checker is what the villagers sweetly call a "natural," as was the case in one Welsh village last year, where the "official" let each rider book any time he fancied to his name, and where one rider humorously overreached himself by booking his time as half an hour earlier than it really was, not discovering till he got on the road again that he had thereby docked himself of half an hour for the next stage.

Sometimes the checker is a club—a little band of practical riders from the local club—who get their work through without muddle or swank. But, oh dear! fifty per cent. of the checks in a six days trial are almost enough to spoil the whole pleasure of the trip. I often wonder why two official cars are not sent on ahead of the competitors with automatic time recorders on board, such as are used for registering men's time at a factory. Three or four of these clocks, slightly modified for the special purpose, would facilitate the checking of the big trials past believing, and would ensure real accuracy.

Petrol Consumption Compared.

The editor has an article of mine in the press relating to petrol consumption, which suggests a technical reason for believing that motor bicycles are very extravagant in the way of petrol consumption. To pave the way for a sympathetic perusal of the article in question, may I contrast a certain car with a certain cycle? A two-seated 8 h.p. car belonging to an acquaintance of mine, weighing 15 cwts., loaded with two passengers, hood, and screen, does nearer fifty than forty miles per gallon of petrol at legal limit.

A certain 3½ h.p. motor bicycle in my own possession, weighing 3 cwts., together with rider, does one hundred miles per gallon. If the consumption of the cycle were equal in efficiency to that of the car (considering weight alone, without taking thought of wind resistance, which acts in favour of the cycle, and ought to give it a lower consumption *pro rata*), the bicycle should do nearly two hundred and fifty miles per gallon—a figure which no motor bicycle of that power can touch in a fair and square consumption trial. Therefore my motor bicycle is in this respect hideously inefficient as compared with the car. Why?

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, E.C., and should be accompanied by the writer's full name and address.

The Amulree Hill-climb.

[4502.]—In reply to the letter of "Fair Play" in your issue of January 3rd, Mr. Adamson's Triumph was debarred from the touring class because it did not comply with the rules, as has been already stated.

"Fair Play's" remarks anent the weights of the machines are without authority, as neither of the machines in question was weighed. JOHN CAMERON.

[This correspondence must now close.—ED.]

Licences for Motor Cycles.

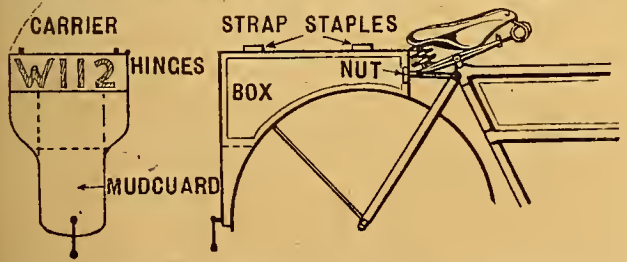
[4503.]—I wish to endorse your suggestion *re* taking out of licences in counties where consideration is shown to motorists. I should like to suggest Staffordshire as being one of these. The Chief Constable is a gentleman and the son of a peer, but what is of much more importance he is a gentleman in his conduct. I believe until recently such a thing as a police trap was unknown, and would have remained so but for the recklessness of a few car drivers. Anyone sending his 15s. to any post office in this county (not, of course, to a county borough) and enclosing his filled up declaration form and a stamped addressed envelope will be assisting the Staffordshire ratepayers. POSTMASTER.

Does an Engine Run Better at Night?

[4504.]—I noticed in *The Motor Cycle* of January 3rd that Mr. Edward O. Dunkley, of Rhode Island, U.S., states that motor cycles run better at night than in the daytime. I have noticed this for a long time, not only with motor cycles but also with cars. I believe that at night the air is more solvent, and therefore more capable of containing petrol vapour, so that a given quantity of air at night or in cold weather is capable of containing more petrol vapour than the same quantity of air in the daytime, or at any time when the atmosphere is charged with water vapour. I shall be very pleased to hear a satisfactory explanation from one of your readers. W. R. B. ANNESLEY.

A Suggested Toolbox and Carrier.

[4505.]—Nowadays, when almost every motor cycle has a fixed luggage carrier, I have often wondered why makers do not utilise the space between the carrier of the rear mudguard as a toolbox or carrying receptacle. It would be inexpensive, out of the way, the rear end of the box would carry the number plate, and the box itself would never be



found superfluous. It might be made of aluminium and lined to match the petrol tank, or sheet iron enamelled to match the frame. If made the same width as the carrier (say 9in.), the lid would have staples fitted for strapping luggage on, and the lid could be opened without taking off the luggage. The accompanying sketch will explain my meaning. NORRIS W. DENT.

Increase of Speed on Partially Raising the Exhaust Valve.

[4506.]—I notice there is some correspondence taking place on the above subject in *The Motor Cycle*. In my opinion the increased speed is due to the compression of the engine being too high, and when the exhaust valve is slightly raised it relieves a little of it. Thus not so much energy is wasted in compressing the mixture, and also we get a better explosion. Petrol engines are more efficient and more economical with a low compression than with a high compression. I cannot see what effect slightly raising the exhaust valve has on making the belt grip.

J. G. RICHARDS.

The End-to-end Record.

[4507.]—I have lately been reading the accounts of the push bicycle records over the End-to-end route, and was surprised to note that the official distance was given as 840 miles when the ferries at Granton (near Edinburgh) and Kessock (near Inverness) are used. I understand that Mr. T. Peck intended to make use of the ferries on his last attempt to break the motor cycle record standing to the credit of Mr. Hart-Davies, who, I believe, did not use the ferries. I should be glad, therefore, to learn what route Mr. Peck followed, as it is obvious that a saving of practically fifty miles is an enormous gain, not only from the point of distance involved, but it also enables the rider to obtain a complete rest and make lengthy adjustments to his machine whilst on the ferries, the Granton ferry, I believe, taking nearly an hour to cross.

CLAUDE E. WALLIS.

Lightweights v. Heavyweights.

[4508.]—In reply to Dr. Gaskell's letter [No. 4495] I should like to point out that never on any occasion have I ridden past a broken-down motor cycle, but have always stopped to enquire if I could assist the rider in any way, and am only too pleased when I am able to do so. On more than one occasion have I towed broken-down motor cycles to the nearest railway station—a thing which a lightweight machine could not do.

I should also like to mention that I am a corn merchant, and have a lot of farm to farm travelling to do. On one of my rounds I have as many as twenty-eight places to call at in one morning. If I am in any place long enough to allow my engine to get cold a little petrol injected in the cylinders will start it as easily as if hot. I have a few times done my rounds on lightweights, but have got tired with the persistent pedalling necessary on anything like a hill, and I can assure him this vigorous pedalling to get to the top of the hills took far more out of me than starting my heavyweight machine twenty-nine times in one morning. And I still "uphold" the heavyweight without the assistance of two other strong young men and a boy.

B. G. DURKIN.

[4509.]—Perhaps my experience of a lightweight motor cycle will be of use to your readers who contemplate having one, and are either past the "hop, skip, and a jump" age, or have a defective gear—in my case, "heart." My medical man told me to give up pedal cycling, but as I have a widely scattered business connection, suggested a lightweight motor cycle, but barred the running to mount business. I bought a Motosacoche, having in view probable breakdowns and its easy conversion to a pedal cycle. This is the second year it has been running, and the mileage, which I noted this year, is over 4,500 miles, and never a breakdown. Weather

has made no difference, and my appointments have always been kept. Speed averages eighteen miles per hour, and after returning from a journey I attend to the machine.

About every 600 miles I scrape piston and cylinder head, and grind valves when necessary. Ignition is accumulator, and has never failed me, and notwithstanding experts' advice to the contrary I shall stick to it.

Three belts have been used, and two are still in use, though getting thin. Tyres are Continental, non-skid back and plain front. I have had one puncture only, and the tyres seem good for another 3,000 miles, which is about what they have done. A sovereign would cover the cost of necessary renewals this year excepting tyres and belts.

The result of having machine is 25% increase in business, and a save of half the time wasted in travelling. Now after a sixty miles run I can slip into my work, which formerly was impossible, and feel all the better for the ride.

To sum the machine up, for reliability, lightness, ease of handling, and cost of running, it is the ideal machine for a business man of limited means and of limited strength.

HARRY SHARPE.

The 1910 Six Days' Trials.

[4510.]—Now that the A.C.U. is beginning to consider the regulations for the 1910 Six Days' Trials, I hope it will go the whole hog and stop all overhauling in controls. The work in controls should be limited to lubrication of magnetos, etc., replenishing tanks, and packing luggage. On no account should the continuous noise from 7 to 8 a.m. be allowed, resulting from starting up engines. A definite limit of, say, fifteen minutes might be allowed at each control. This might be made shorter if the competitors were made aware of the exact position of the control. Finally, though I am afraid I shall be laughed at, I strongly object (for it is bound to do the motor cycle movement a deal of harm) to seeing men or machines travelling from one end of the country to the other wrapped up with spare tubes. Abolish spare tubes and bring tyres into account, then we may hope for intelligence and improvement in that department.

F. C. MUSTARD.

P.S.—I hope the A.C.U. will not put its officials behind the hedges for surprise controls. Anyone who has ridden in a 200 mile non-stop trial at twenty miles an hour will know what to expect when there is a week of twenty miles per hour awaiting him.

The 1910 T.T. Race.

[4511.]—As a prospective competitor in the above race, now that the provisional regulations have been published, I should like to make a few remarks and suggestions.

I sincerely hope that practising will be allowed on more than seven days previous to the race. The course selected is well known to be a very "tricky" one, and with practising only permitted from daybreak to eight o'clock each morning, it is extremely doubtful if any rider who is new to the course could accustom himself to riding up to the necessary safe limit of speed in so short a time. May I suggest that either a fortnight's practising be arranged for, or that competitors be allowed to ride round the course all day if they wish, provided they do not exceed the legal limit after 8 a.m. It is well known to all who have taken part in the previous races that the inhabitants of the island, including the press, are very keenly interested in these events, and no unnecessary or hampering restrictions are imposed.

I should like to propose also that the A.C.U. again promotes a hill-climbing competition in the island, and hope it will not be necessary to have two, especially on the same day. It would be much better for the competitors if the climb were held before instead of after the Tourist Trophy Race, as it would then be unnecessary to have to set to work to "tune up" immediately after the big event is over.

FRED C. BAGSHAW.

Ease of Starting.

[4512.]—I think that "Ixion" is a little bit "off the line" when he says that paraffin injections before starting mark an imperfect machine, at least I so read his paragraph "Ease of Starting." As he knows very well, it is only necessary to ease the piston rings (a) when the piston is a good fit in cylinder, or (b) when using thick oil in cold weather. Now, as an accurately fitting piston means freedom from knocking, good compression and full efficiency, it follows that it must be everybody's desideratum. Therefore, it cannot be a defect. In my opinion, a new machine that does not require a dose of paraffin or petrol before starting, to free the rings, indicates that the maker did not know his business.

My machine now suffers from a loose piston, resulting in a permanent knock and loss of efficiency. No paraffin injection is consequently necessary, though it was for the first 5,000 miles. Yet I am going to spend £3 to get back a good fitting piston and cylinder, and with it the need for a paraffin injection before starting from cold. If "Ixion's" argument means anything at all, it means that I am simply frittering money away to secure an undesirable state of affairs, which is not the case.

No, "Ixion"; it was because the machines in the Six Days' Trials were new that they required paraffin injections. It is not a defect. Why they did not start easily afterwards is more than I can say, however. E. M. OLIVER.

Another Rejuvenated Tricar.

[4513.]—There has been considerable interest of late in tricars, and especially of the type nearest approaching the light car for comfort and sociability, and I therefore venture to send you a photograph of a tricar I have been using for some time with success. It is of small power, 4½ h.p. Auto-moto engine with two speeds, and, as you will see by the photograph, the three seats are built the same height, and

Home-made tricar referred to in Mr. G. P. Sentance's letter.

are all set on strong spiral springs. It is exceptionally comfortable to both passengers and driver, and, being seated in this way, there is scarcely any wind resistance.

I can travel from eighteen to twenty-four miles per hour with three persons up, and have not as yet been stopped by any hill, the low gear being very reliable.

I may say the tricar was rebuilt to my own idea, and I had considerable trouble in getting it done, as the local firm at first said it would not be safe. Now they have nothing but praise for it. G. P. SENTANCE.

The Transmission Question.

[4514.]—I have read with usual interest "Occasional Comments" by "Ixion" in last week's issue of *The Motor Cycle*, and would like to take the liberty of making a few comments on the matter of transmission. I cannot help thinking that there is a tendency on the part of some English motor cyclists who are not thoroughly familiar with the advantages of chain drive to cry in favour of the belt drive, and until they—like myself—have a chance of riding a machine equipped with a scientifically applied chain drive, I can quite understand their feelings. Until this last year I was greatly in favour of the belt drive, but after I had given the Indian chain-driven machine a thorough trial and found for myself what a comfortable and practical drive the chain gave, I had no further use for the belt. I can assure motor cyclists in this country that my opinion was not changed because I decided to sell Indians in this country, as it must

be very well known that the Hendee Manufacturing Co. did supply a belt-driven model in 1909.

This machine was fitted with Shamrock-Gloria belt and the standard English belt rim on the rear wheel. To the engine was fitted one of the best designed belt pulleys I have ever seen, and it was quite optional to me whether I sold these machines with the belt or chain drive. "Ixion" says: "I have little doubt that as the Americans learn to make better belts we shall hear less and less of the chain drive in the States." Possibly this may be the case; if so, it can be put down to two reasons. Firstly, because there are at the most only one or two leading manufacturers who understand how properly to apply a chain drive to a motor cycle; and, secondly, and undoubtedly the principal reason, is that the belt drive is very much cheaper to manufacture. On the other hand, I maintain that the chain drive is far cheaper for the rider. In the first place a chain will outlast two or three canvas and rubber belts of the best makes; secondly, a chain sprocket on the engine will last as long as a belt pulley, and when renewed costs about one-third as much. The sprockets on the counter-shaft and rear wheel, as well as the longer chain, will last many thousands of miles, and when a new one is required it costs no more per foot than a first-class belt.

As for the rigidness of the chain drive, I can only say that, when the clutch is properly adjusted, there is no apparent slip when running at a steady pace, yet it is very apparent that there is a slip in starting and after switching on and off, which is proved by the fact that rubber-studded tyres will last as long as, if not longer than, on a chain-driven Indian than on belt-driven machines of other makes.

It is interesting to hear indirectly that some of the largest motor cycle manufacturers in England are experimenting with chain drive, and the possibilities are that we shall see other machines than the Scott, P. and M., and Indian, fitted with chain drive in this year's T.T. Race.

W. H. WELLS.

[4515.]—We have read with much interest the paragraph in the issue of *The Motor Cycle*, January 10th, under the above heading, but we feel that the writer is speaking without knowledge of a chain drive. He states that a belt which lasts 2,500 miles seems to be a most unusual thing, but we can assure the writer that if he used the chain drive, 10,000 miles would be a very small distance, and with regard to smoothness of drive, etc., we are willing to demonstrate to Mr. Olsson, or any other person interested, that with a 3½ h.p. machine and a sidecar with 12-15 stone passenger we can start from a standstill, just as Mr. S. F. Edge would do with a six-cylinder car and plate clutch, which, we think, should satisfy anybody. We are glad to note that Mr. Olsson admits that advocates of chain transmission are becoming more numerous lately, and we quite agree with him. Surely this is because chain drive proves itself more efficient and reliable than belt drive.

PHELON AND MOORE, LTD.,
W. PRATT, London manager.

Water Cooling on Motor Bicycle Engines.

[4516.]—Your contributor, "Ailette," has written an interesting and convincing article on the subject of water-cooling for motor cycle engines. May I remind him of the Mototri-Contal 2¼ h.p. tricar, which flitted before our notice for a brief week in the summer of 1905. This had a really comfortable coach-built front seat, and it was fitted with an engine that would not be considered large on a present-day lightweight. It had a hub epicyclic gear giving two speeds, about 8 to 1 and 20 to 1, but no reverse. The water-cooling on the thermo-syphon system was the life and soul of this diminutive motor. It went through the A.C.U. Six Days' Trial, in which I was an official, and several times I was the passenger. The driver was a real heavyweight, yet it climbed Birdlip on the last day without shedding the passenger. It never faltered, and it never once knocked. Of course, it boiled like a steam car on long climbs, up which it plugged steadily at about five to eight miles an hour; but it never appeared distressed. It averaged ten to fifteen miles an hour over undulating country—wonderfully good for two people on 2¼ h.p.

Water-cooling was the secret of its success, and I think this method might with advantage be more widely adopted.

J. W. G. BROOKER.

Cost of Running a Small Car.

[4517.]—I have been running a 5½ h.p. O.T.A.V. four-wheeler for about ten months, and as the details of the expenses may interest some of your readers I enclose them, with one or two remarks.

The little car has a single-cylinder engine 100 × 110 mm., accumulator ignition. It is air-cooled by a fan and air jacket, and has two speeds forward. Drive is by a chain from engine to a counter-shaft (parallel to the back axle), on which is carried a two-speed epicyclic gear box, and thence to the driving wheels by ordinary motor cycle belts, ⅞in. wide by 7ft. 6in. long. There is no differential, belt-slip being sufficient to allow one wheel to over-run the other. My car was not new, having been used in trials by the agents, and its total cost with accessories was £98 9s. 6d.

RUNNING COST.	£	s.	d.
Petrol (58 gallons)	3	6	6
Lubricant		6	0
Tyres (two Clincher Dreadnought, 26 × 2¼, and slight repairs)	4	13	6
Repairs	11	11	0
Licences, registration, and tax	3	7	0
Insurance	4	10	0
Garage fees	1	19	0
Miscellaneous		19	0
Total	£30	12	0

Mileage, 1,125; miles per gallon petrol 19.4 (large waste); running cost per mile, 6½d.

REMARKS.

(1.) *Petrol.*—Much was wasted through experimenting and a leak in the tank that could never be stopped for long. Running consumption, I reckon, about thirty-five miles per gallon (gear, 7 to 1 on top).

(2.) *Tyres.*—I have not had a puncture yet. The rear tubes are filled with Miraculum.

(3.) *Belts.*—Give a good deal of trouble, being too short and too small. Turning corners, too, is very hard on them as they are made to slip. One occasionally breaks or comes off, and is lost without being discovered in time.

(4.) *Speed.*—I can average about 18 or 19 m.p.h. over a run of, say, fifty miles under ordinary conditions. Gear is low, and the car can take hills up to 1 in 16 or 17 on top with two up.

(5.) *Repairs.*—These include a new epicyclic brake drum which cracked; new pulleys, one having dropped off and was lost; a new chain, and sundry minor items. The prices charged for replacements are, in my opinion, high. In spite of all this, when all the weak points have been eliminated, the car is very satisfactory and economical to run. It weighs about 450 lbs., and the engine is a very good one, having 1⅞in. valves to its 4in. bore, and an a.o.i.v.

I have not done a very big mileage, because I ride a motor bicycle for solo work.

SILEMA.

SUMMARY OF OTHER CORRESPONDENCE.

Osmond Hill writes in strong praise of the Lincoln Elk motor bicycle. The machine was purchased last May, and with the exception of one broken exhaust valve has given no trouble.

EXPERIENCES WANTED.

STAMPS SHOULD BE SENT FOR FORWARDING REPLIES TO QUERIES UNDER THIS HEADING.

"K 2305" (Liverpool) would like readers' experiences of A.C. tandem tricars, particularly as to reliability and good material.

"R. B." (Plymouth) desires users' experiences of the Triumph plate clutch model, particularly as regards starting on hills.

"G. J. H." (Henley-on-Thames) would like experiences of the Zenith Gradua gear used with and without a sidecar. Also of a Triumph fitted with Gradua gear and used with and without a sidecar.

"A.E.L." (Heavitree) would like users' opinions of the two-stroke Scott as to suitability for sidecar work in hilly country, and also if there is trouble by reason of the charge of gas firing in the crankcase.

A selection of questions of general interest received from readers and our replies thereto. All queries should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, E.C., and whether intended for publication or not, **must be accompanied by a stamped addressed envelope for reply.**

Small Water-cooled Engines.

I want to procure a small water-cooled petrol engine to drive a lathe. Please say where one would be likely to obtain a 3 to 4 h.p. engine, water-cooled.—J. G. P.

Small water-cooled engines of the size you require can be obtained from the Stevens Motor Mfg. Co., Ltd., Wolverhampton; White and Poppe, Ltd., Coventry; and Aster, Ltd., Wembley Park, Middlesex.

Worn Tappets.

The shafts of my valve gear (1907 machine) are loose. As the parts are, of course, hardened, could a local motor mechanic put this right? If so, kindly tell me the proper thing to do. The tappets are considerably worn, but the pinions and cams are little the worse for wear.—H. A. B.

It entirely depends upon the skill of your local mechanic. If he is a really skilful repairer, and used to repairing motor bicycles, he will probably carry out the work effectively. You do not say where or how the shafts are loose. We should recommend you to obtain any spare parts required from the makers of your engine, as they would fit better and could be obtained from stock.

How to Prevent Knocking on Hills.

I should be glad if you would tell me what to do when engine of my motor cycle starts knocking on hills. It is a free engine Humber. I cannot pedal, as you advise another querist, but I have tried retarding the magneto spark lever, opened and closed throttle and air, and still the engine knocks.—J. H. E. (Liverpool).

First of all check over the timing and see if the spark is too much advanced, and, secondly, dismount the cylinder, and remove all the carbon deposit on cylinder and piston heads. If the engine still knocks or pounds, you do not manipulate the levers properly, or there is a loose or worn bearing in the engine. The correct way to drive when climbing a hill is to increase speed on approaching the rise by opening the throttle and adjusting the air lever to suit. As soon as the engine shows the slightest falling off in speed, close the air lever gradually to enrich the mixture, and open the throttle fully if the gradient demands it. The magneto spark lever should not be retarded unless the engine continues to fall off in speed after the air lever is closed.

Local Taxation Licence.

(1.) In the official form sent to be filled up this year I notice a paragraph which I have never seen before, stating that the registered number of the car or cycle must be given. I suppose the authorities do not mean from this that the licence is not transferable? What I mean is that I expect in a few days to sell my old machine and buy a new one. As I shall take care not to have two machines at the same time, I presume one 15s. licence will be sufficient. Please let me know if this is so. (2.) With reference to the registered numbers. I am expecting to sell a 1908 Triumph motor cycle and buy a 1910 model of the same make, and there would thus be absolutely no change in the particulars registered. In these circumstances could I merely transfer my number from the old machine to the new one?—V.G.M.

(1.) As stated last week, we are advised that there is no legal obligation to furnish the particulars referred to. Certainly the carriage licence is transferable, as it allows you to *keep* any one motor cycle, consequently one licence will be sufficient for several machines in one year, provided, of course, you do not own more than one at the same time. (2.) You must take out a fresh registration for the new machine, though if you wish to retain the old numbers you may probably do so if you ask leave of the authorities.

Easy Starting. Oiling Clutch. Tight Belt.

My motor bicycle is fitted with a Mabon clutch and handle-bar control carburetter. (1.) Would White's economiser be an improvement as regards (a) power, (b) easy starting, (c) slow running in traffic (I live in London), and (d) petrol consumption? (2.) Would my 3¼ h.p. machine take a sidecar, and if so with what gear? I do not mind occasionally assisting the engine with the pedals. (3.) Can one give too much oil to the clutch? (4.) What is the result of having the belt too tight except risk of breakage?—W.S.H.

(1.) First of all, try stopping up one of the main air holes, and if an improvement is noticeable, an adjustable main air intake, such as the device in question, will help you considerably as regards power at slow speeds and ease of starting. (c.) Also slow running in traffic. (d.) We are, however, doubtful if it would improve the petrol consumption, except that it would enable a smaller jet to be used. (2.) Your machine would take a sidecar on fairly level roads with a 5¾ to 1 gear. (3.) You can, of course, give too much oil to this clutch, as an excess would leak out and make a mess, and probably get on to the belt. Frequent lubrication in small quantities is best. (4.) If you have the belt too tight you wear the engine bearing to an excessive extent, and probably tear out the fastener.

Inland Revenue Tax Exemptions.

I use my motor bicycle for attending markets, fairs, sales, etc., in connection with my business, and use it for business alone. I held a licence in 1909, but do not intend to take out one for 1910 if I am not legally required to do so. Kindly advise.—N. D.

We are afraid you will not be exempted from paying the Inland Revenue licence, as your machine is not specially constructed for the transport of merchandise.

Loss of Power. Replacing Carburetter.

I do not seem to get the power I ought to out of a new 1¼ h.p. lightweight. The engine is quite new, but I have got a very old pattern carburetter fitted. It has no float chamber, the petrol runs direct to the needle, and it seems to me that sometimes the engine gets too much petrol, at other times not enough, and then it misfires. I am told by a local maker that by fitting an up-to-date carburetter I shall get double the power. At present it will not climb any of the little hills about North London. I can also hear a little hiss of wind past the inlet valve. Would this cause a noticeable loss of power? It is very difficult to make a good joint, as the whole of the inlet valve screws into the head just over the exhaust valve. How can I make a good joint of such a valve?—W.C.B.

We quite agree that the new carburetter would improve the power immensely, and we would recommend you to have one fitted without delay. The hissing is due to a leakage and a loss of compression. So long as this exists you cannot expect the engine to give full power. It is not good practice to screw the valve seat into the head. To make a good air-tight joint, see that the surfaces are perfectly flat and clean, then fit a soft copper and asbestos washer, and paint the joint with fish glue obtainable from most marine stores.

MOTOR BICYCLES FOR SALE.

09 Triumph, not been ridden 200 miles. Polkey lamp and generator, trimote horn, new last August; price £37.—Wilson, 19, Wellington St., Bradford, Manchester.

BIGGEST Bargain ever offered.—3½h.p. Quadrant, in good running order, complete with belt, coil, accumulator, horn, tool bag, number plates; £4 19s. 9d. Booth's Motories, Halifax.

3½h.p. Minerva, magneto, spring forks, footrests, 4 h.b.c., lamp, horn, watch, spares, tyres good, Watawata belt, new cylinder; £18, offers.—Pearson, Lyear, Bedale, Yorks.

EX, 5½h.p., twin Rex, spring forks, separate generator lamp, horn, stand, and new spare tube, suit tecar; £16 16s.; exchanges considered.—Motor Exchange, Westgate, Halifax.

h.p. Humber, chain driven, free engine clutch, Longuemare carburetter, Dunlops, non-skid on back wheel, od condition throughout; £8.—Bate, 23, Park Rd., lborne, Newton-le-Willows.

EADY for Delivery.—1910 Premier, 3½h.p., twin quite the coming success, and undoubtedly the est little jiggers on the market; 50 guineas; exchanges ntertained; send for list.—Hardman, Stockton Heath.

h.p. 1906-7 Norton, in new condition, and good going order, guaranteed, recently overhauled, Palmer front, ncher back, coaster, H.B. switch, registered; ready road; £9, near offer.—Moore, 19, Cowley Hill, St. lens.

IVERPOOL Motorists should, to protect their interests, buy Triumph, Douglas, Scott, and F.N. tors only from the responsible official agents, Hitchs, Ltd., 74, Bold St., who alone can substantiate makers' guarantees, and also supply spare parts from ck.

RIUMPHS.—Hitchings, Ltd. (the official agents), have several second-hand machines for sale at low prices 07, 1908, and 1909 models; all guaranteed; inspection invited.—Hitchings, Ltd., 74, Bold St., Liverpool.

COTT 2-stroke 2-speed Water-cooled Motor Cycles (for which Hitchings, Ltd., are the sole Liverpool and strict agents) should be ordered now to ensure early livery; send for descriptive catalogue.—Hitchings, Ltd., Bold St., Liverpool.

IGHTWEIGHT Douglas and F.N. motors, latest models in stock at 74, Bold St., Liverpool.—Hitchs, Ltd., are the sole agents, and invite enquiries.

h.p. Twin V.S., Truffault forks, magneto, Clincher studded butted tubes (unpunctured), Whittle belting and enamel unscratched, absolutely new condition, with 1909 Chater-Lea rigid sidecar, complete; £29 .; separate or exchange.—7, River View, Ashton-on-ble.

SECTION III.

Cruarvon, Denbigh, Flint, Cheshire, Derby, Stafford, Shropshire, Montgomery, and Merioneth.

10 Triumphs; delivery from stock.—Altrincham Garage, 1, Church St., Altrincham.

09 Triumph, used ten weeks; owner going abroad; £40; must sell; complete.—H. Marston, Rock ry.

OTO-REVE, new August, 1909, Druids, Watawata, adjustable pulley; £22 10s.—V. Johson, 68, Radne St., Derby.

WIN Rex de Luxe, magneto, cantilever, twin tyres, spring forks, Roc clutch; offers.—68, Wellington North, Stockport.

h.p. Minerva, vertical, M.O.V., 26in. wheels, perfect and sound condition; £6 10s., bargain.—Meredith, ester Rd., Over Winsford.

ARGAIN of a lifetime.—1909 3½h.p. Rex, beautiful machine, complete; £34; buying car.—3,879, *The Motor Cycle* Offices, Coventry.

h.p. Raleigh, chain driven; cost 80 guineas; little used with new covers; price £15.—P. Robinson, k Hill, Egginton, near Derby.

h.p. Brown, magneto, new December, run 100 miles, spring forks, variable pulley, all accessories; £34 quick sale.—Henshaw, wheelwright, Stockport.

09 Triumph, enamel and plating as new, machine and engine guaranteed perfect throughout, searchlight lamp, horn, etc.; £37.—Browne, Beaconsfield, Oxton, Birkenhead.

RIUMPH, 1907, H.B. control, splendid condition and appearance, accessories, and spares; any examination here; £24, lowest; no offers.—Gregory, Sir John Arren Hotel, Ilkeston.

ARGAIN.—3½h.p. Quadrant, 1907, like new, low, fast, reliable, spring forks, stand, Brooks B100 saddle, new Shamrock studded tyres, etc., etc.; accept £18.—Gibbs, Mill Hill, Sandbach, Cheshire.

h.p. Roc, magneto, two speeds, free engine, handle starting, non-skid device, absolutely impossible to turn machine over, will take sidecar anywhere, in practically new condition throughout; sacrifice £32. — R. ge, Leawood, near Matlock.

MOTOR BICYCLES FOR SALE.

SECTION IV.

Nottingham, Lincoln, Leicester, Rutland, Northamptonshire, and Warwickshire.

3½h.p. Birmingham Quadrant, 1910 Amac, ball bearing magneto; also

3h.p. Birmingham Quadrant, handle-bar control, carburetter, both guaranteed; cash offers.—Reg. Samson, Ladywood Rd., Birmingham.

TRIUMPH, 1909, scarcely soiled; offers wanted.—Trelawney, King Edward Rd., Coventry.

3½h.p. 1907 Triumph, magneto, spring forks, thumb switch, splendid condition; nearest offer to £24.—Below.

3½h.p. 1907 Model Triumph, new June, 1908, equal to new throughout very little used; £28, or nearest offer.—Frank Hall, Triumph Agent, Broughton Astley.

KERRY, 2¾h.p., fast, reliable, low frame, 26in. wheels, long bars, excellent order; £8 10s.—67, Southgate, Sleaford.

2½h.p. Minerva, Dunlops, Whittles, just been overhauled; bargain, £8, or offer.—W. Lock, Heeley Rd., Bournbrook.

MOTOSACOCHE, complete, spares, spring forks, new back tyre, good condition; £13.—Daws, 35, Tennyson St., Leicester.

3¼h.p. Rex, 28in. wheels, non-skid R.O.M., trembler, two accumulators, spares; £7.—Gibbins, Barcot Green, Birmingham.

1908 3½h.p. Rex Motor Cycle, splendid condition; will ride 50 miles to a buyer; owner going abroad; offers.—George Rice, 116, Sanvey Gt., Leicester.

3½h.p. Triumph, late 1908, and brand new 1910 Chater-Lea coach-built sidecar, cycle in perfect condition, Palmer cord tyres, Michelin butted tubes one spare; £35 10s., or sell separately.—3,887, *The Motor Cycle* Offices, Coventry.

IVAN B. HART DAVIES wishes to sell his End-to-end Triumph, 85 by 88 engine, two gallon tank, special handle-bars, spare butt-ended tube, all tools and spares, lamp, horn, etc., run 2,000 miles, as good as new; £40 cash.—Apply, I. B. Hart-Davies, Bank St., Rugby.

3½h.p. Humber, two-speed and free engine, new last June, since overhauled by makers and fitted with 1910 improvements, including Druid spring forks, plain connecting rod bearing, new footboards and control, large belt pulleys, complete with lamp and tools, Dunlop tyres (unpunctured); £34, or nearest; bargain.—G.S., 37, Northumberland Rd., Coventry.

SECTION V.

Norfolk, Suffolk, Cambridge, Huntingdon, and Bedford.

3½h.p. Rex, spring forks, spring seat-pillar, long handle-bars, new Continental tyre; £7, or exchange with cash twin or tricar.—Dyball, Raynham, Norfolk.

5-6h.p. Twin Rex, magneto, two-speed, new, only run 100 miles; extraordinary bargain, £35, or near offer.—Mann, Egerton, and Co., Ltd., Norwich.

3½h.p. Matchless (cyl. 85 by 88), late 1908, first-class order, had very little use; owner using car principally; magneto in tank, R.C.M. steel studded tyres both wheels, Brooks latest padded saddle, Matchless spring forks and stand; £20.—Mayor Eggington, Leighton Buzzard.

SECTION VI.

Worcestershire, Herefordshire, Radnor, Brecknock, Monmouth, Glamorgan, Carmarthen, Cardigan, and Pembroke.

MINERVA Lightweight, 1¾h.p.; exchange for push bike, or sell cheap.—Devey, Wassell Grove, near Stourbridge.

1908 N.S.U., 3½h.p., magneto, B. and B. handle-bar control, spring forks, condition and running order perfect; £22.—Ault, Usk, Mon.

SECTION VII.

Gloucester, Oxford, Buckingham, Berks, Wilts, and Hants, and Channel Islands.

2¾h.p. Minerva, racy pattern, nearly new engine; £8 10s.—Smith, Luther Cottage, Odd Down, Bath.

TRIUMPHS, 1910 models in stock; order at once for early deliveries.—Sole Agent, Longman, Fisherton, Salisbury.

1909 Triumph, seven months old, run 1,500 miles, new tyre back wheel, perfect condition; £32.—G. Lathbury, H.M.S. Britannia, Portsmouth.

WE WANT TO SAVE YOU MONEY. IT CAN BE DONE.

But for the introduction of the

"CHEMICO"
TYRE STOPPING

many a cycle and motor cycle cover which is now rendering its owner good and useful service would have been scrapped, and the cost of new covers incurred.

"CHEMICO"
TYRE STOPPING

is a plastic material which, placed in the cut or gash, quickly amalgamates with the material, to which added, making a perfect repair. Easy to use, is not a liquid, cannot fall out, quickly sets, and makes a permanent repair.

Hundreds of apparently hopeless cases have been saved; if you have a cover badly cut or gashed, do not scrap it until you have given this preparation a trial.

THE RESULT WILL ASTONISH YOU.

£60.—10-12h.p. Lanchester, water-cooled, 5-seater, new tyres, re-painted, perfect order, many spares.—3,847, *The Motor Cycle* Offices, Coventry.

4½h.p. De Dion Phaeton, two speeds, perfect condition; £18 10s., or exchange.—128, High Rd., Tottenham.

9-11h.p. Star, tonneau, three speeds, reverse, equal wheels, complete equipment; £60; very good condition; trial.—Above.

CAR, 9h.p. Rex, seats four, three speeds and reverse, in splendid condition; exchange for motor cycle and cash, or sell £75.—83b, High St., Sutton, Surrey.

LIGHT 2-seater Car, good gear box, three speeds and reverse, with or without 4½h.p. De Dion engine, in capital order; price £19, or £15.—Hitchcock, Rattlesden, Suffolk.

10-12h.p. Tony-Huber, 4-seater, splendid condition, three speeds, reverse, excellent tyres, hood, Stepney wheel; £58; consider smaller car part.—4, Frances St., Woolwich.

6½h.p. Genuine De Dion Modern 2-Seater (buckets), Dunlops, artillerys, two speeds, reverse, cardan drive, screen, lamps, smart, reliable; £37.—D., 59, Minet Av., Willesden.

10-12h.p. Pick 4-seated Car, 2-cyl. engine, been standing in coach-house over a year; must sell; £20, or exchange motor cycle.—Apply in first place, Turvey and Co., Garage, Sunderland.

DARRACQ, 15h.p., in good condition, County screen, Cape hood, detachable back, forming 2-seater; £115; good modern motor cycle taken in part exchange.—Heybourn, Motors, Maidenhead.

10-12h.p. M.M.C., Daimler 2-cyl engine, roomy tonneau body, make a splendid van up to one ton; must clear; £35, or exchange Triumph motor cycle. — Turvey and Co., Motor wks., Sunderland.

PANHARD Car, 6h.p., 2-seater, water-cooled, three speeds, reverse, electric ignition, artillery wheels, pneumatic tyres, wheel steering, good running order; trial given; £12 10s.—Shackleton, Livingstone House, Bolton Woods, Bradford, Yorks.

ENGINES.

2½h.p. Vertical Engine, complete, air-cooled; £1.—Weeden, 35, Bow Lane, Poplar, E.

GAS Engine, ¼h.p., and Crypto enclosed dynamo.—Full particulars, 119, Gordon Rd., Ealing.

ENGINES.—Roc, 4h.p., single-cyl., new 1910 type; early deliveries.—A. W. Wall, Ltd., Birmingham.

3h.p. Automoto Engine, cylinder damaged, Acetyphote, F.N. and Longuemare carburetters; £3 or offer.—Lee, Woodton, Bungay.

FAFNIR Engines; your old engine taken part payment for 1910 model, 80 by 90.—Genn, Motor Engineer, Wimbledon.

QUADRANT Engine, 3h.p., genuine Birmingham works built, complete, brand new; offers. — Reg. Samson, Ladywood Rd., Birmingham.

QUADRANT Engine, 2½h.p., also tank and surface carburetter, new, never used; £4 4s., or near offers.—Apply, Box L903, *The Motor Cycle* Offices, 20, Tudor St., E.C.

AERIAL Model Motors.—Model practical air or water-cooled ½h.p. petrol motors, 9s. 9d., machined; profusely illustrated list, 80 sizes, 4d.—Littleover Aerial Dynamo Works, Derby.

4½h.p. Bradbury Engine, two-speed gear box, clutch, carburetter, in first-class condition; can be seen running on tricar by appointment; £11, or nearest offer.—Strickson, 91, St. Stephen's Rd., Upton Park.

3h.p. Fafnir Engine, complete, carburetter, silencer, fitted with cut-out, recently re-bored, dome top piston fitted, guaranteed in good condition; can be tried; price £4 15s.; buying 4½h.p. Fafnir.—71, Avarn Rd. Mitcham Rd., Tooting.

CLEARANCE Bargains.—Chater-Lea two-speed gear, wants new pinion, £2 10s.; Collier silencer, large, 6s.; two Peugeot 5h.p. ditto, 4s. each; coil, large, Nilmelior trembler, 15s.; Chater-Lea tank, 21in. long 8½in. deep, 15s.; Minerva ditto, 24 by 8, 10s.; De Dion car coil, non-trembler, 25s.; 4½h.p. De Dion water-cooled cylinder, 20s.—Genn, Motor Engineer, Wimbledon.

3 *Grand Prix.* 8 *Gold Medals.*

As a chain is only as strong as its weakest link, a belt is only as efficient as its least considered essential.

The essential links in motor belting construction—Maximum effective pulling surface: Elimination of stretch; Tensile strength; Flexibility; Centring of core; Prevention of twisting, ends breaking, and surface cracking—when evenly considered and supported by suitable materials and experience, ensure a perfect whole.

Camel Belting, owing to its uniform wear, due to scientific construction, is offered and sold as being the nearest possible to the ideal.

The 1910 Competition Programme.

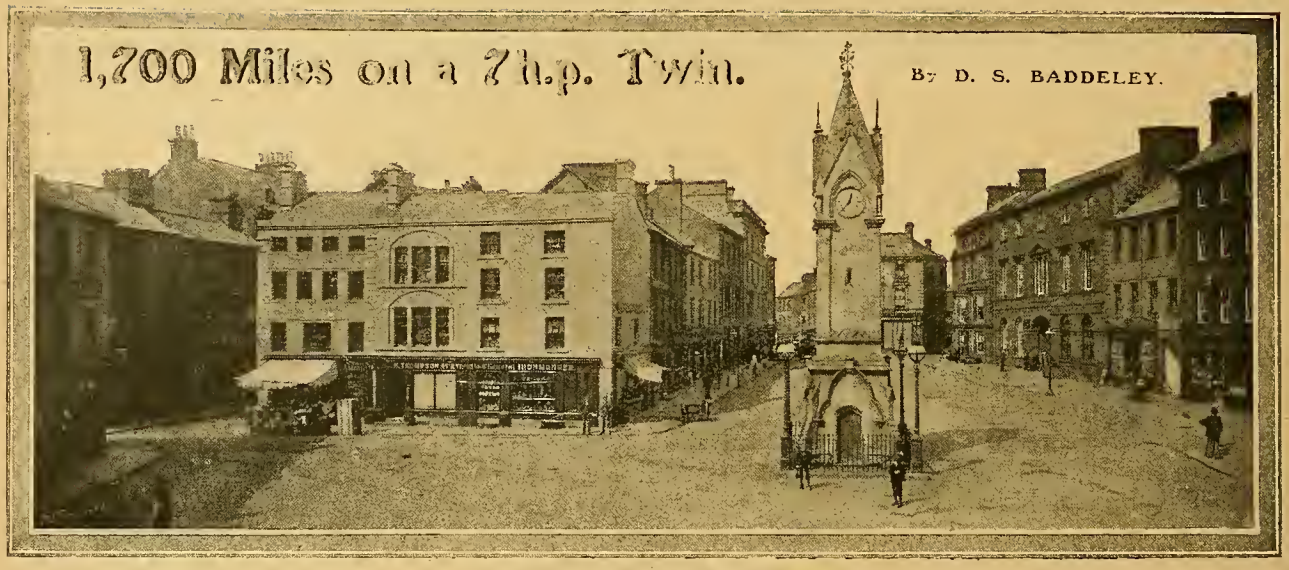
NEXT Saturday, the motor cycle competition ball will be set rolling with the A.C.U. Quarterly Trial, and what a formidable list the 1910 fixtures make! The numerous competitions indicate in no uncertain fashion the growing activity in the pastime, but it is likely that the present year will witness the weeding out of superfluous trials. At present some of the projected trials are mere repetitions of other events which have already achieved fame and importance. Consequently it is hardly likely that manufacturers will spend money by entering their riders in the lesser-known events, as already the expenses incumbent upon demonstrating to the public the capabilities of the modern motor cycle form a heavy year's total. Moreover, it will be generally admitted that half a dozen really important and well supported events are likely to do far more good than an abundance of unrepresentative and poorly supported trials. We are not here referring to closed events organised by provincial clubs. The more of these trials the better, as we realise that they are good for the pastime, and do much to stimulate and sustain local interest in motor cycles. We were recently asked by a new firm of manufacturers to enumerate the most important of the events already decided upon. On scanning the list we could not help but be struck with the similarity of some of the competitions, and it does seem a pity that manufacturers should be called upon to support two events of a practically similar nature, when one really big event would not only halve the expenses but most probably be productive of more real good. This is no doubt the opinion of a number of firms.

Taxation Exemptions.

DURING the last three or four months we have made frequent references to the question of the local taxation licence and the exemptions which were granted by the Inland Revenue authorities prior to the time the duty of collecting the tax was handed over to the various borough and county councils. One exemption in particular which was invariably granted by the Inland Revenue Department (the clause is still printed on all the declaration forms which we have seen in circulation) refers to motors laid by and not used at any time during the year. This exemption clause has been in operation during the last twenty years, but recent correspondence has shown that in some cases the local officials have insisted upon payment of the duty whether the motor was used on not. This seems farcical, and we should say that payment of the duty could not be enforced by any officer in the case of a motor kept but not used. We have had personal proof during the last few weeks that all local officials do not insist upon payment of the duty under the circumstances enumerated. Consequently our advice to any reader who has a motor cycle which he does not intend to use at any time during the year is to address a courteously worded letter to the clerk to the borough or county council in whose district he resides explaining that he does not intend to use the machine for a time, and that immediately it is put on the road the necessary licence will be taken out within the stipulated twenty-one days. In nine cases out of ten we feel certain that the reply will be to the effect that payment for a licence will not be enforced until the motor is actually used.

1,700 Miles on a 7h.p. Twin.

By D. S. BADDELEY.



Devonshire Street and Market Place, Penrith.

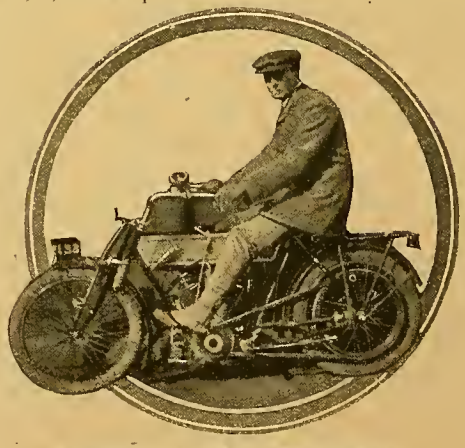
IF this history is neither strange nor eventful it is veracious, and although many men may have accomplished a bigger mileage in sixteen days than I did, yet I feel that I may look back on my trip with pleasure and perhaps a little pardonable pride.

The story opens in a suburb of Glasgow on Wednesday, July 28th, 1909, and there at 6.30 p.m. the writer is awaiting the arrival of two fellow clubmen who have offered to see him safely off the premises.

At 6.45 p.m. No. 1 arrives on a 1909 Triumph; a 4½ h.p. Minerva is a bad second, turning up at 7 p.m. I have discussed my route with No. 1, and we both talk it over with No. 2, and having wheeled out my 7-9 h.p. Baddeley, with Peugeot engine and other component parts (some of which will be referred to later), we start away through East Kilbride to Hamilton, where I fill up with petrol, and my friends decide to return as rain has commenced. I push on southwards, and at Larkhall an umbrella coat which has accompanied me through five London-Edinburgh jaunts is unstrapped and put into commission, for the rain is now coming down in sheets. The front plug has been industriously sooting itself up meanwhile, and at Lesmahagow I decide to clean it. This done we run well over Douglas Moor to Abington, where an A.A. scout advised caution. The water is starting to run down my neck and blow past my wind cuffs, so, traps or no traps, I open up a bit and soon reach Elvanfoot. Here the front plug indicates in the usual manner that it has managed to get sooted up, so again it comes out and is cleaned, and then at an increased pace we travel to Nethercleugh.

By this time the rain has found its way down my neck, up my arms, and into my shoes, but the 7-9 h.p. does not complain, and after lighting up we soon reach Lockerbie, then Ecclefechan, Gretna Green, and over the Solway Firth into good old England. It is light work now to Carlisle, and at 11 p.m. I arrive at the County Hotel, and have a hot bath while my clothes are drying.

Pouring with rain on Thursday, but I start at 9 a.m., running through Penrith and so on to Shap. On this hill I run into an especially moist cloud about four miles from the top, and the rain runs off my face and down my neck, which is not pleasant. Prospects improve at Kendal, through Kirkby Lonsdale and Clapham to Settle. At Hellifield my front wheel drops into a huge pothole full of water, which splashes on the high-tension terminal of the magneto and causes misfiring in the back cylinder. Soon Skipton is reached, and then follows the string of big towns, with bad going and many delays. At Leeds I refill (man and machine), then on through Wakefield, Barnsley, Sheffield, and Derby, to Leicester. Here I fill up again (petrol only this time), and raise my gear from 3¾ to 1 to 3½ to 1. At Market Harborough a belt-fastener breaks, so I replace it and close up the adjustable pulley still further. Northampton is reached in due course, then Dunstable; here I stop for a cup of Bovril, and raise my gear still higher rather than shorten the belt. From Dunstable to St. Albans seems to take no time at all, and thence I dodge across country through Enfield to Chingford, arriving there at 10 p.m. Two days, 438 miles, mostly over wet roads. [Unless, as in the writer's case, it is desired to call at Leeds for the purpose of visiting friends, there is a much better road for motor cyclists journeying from almost any part of central Yorkshire to London. After Skipton all signposts pointing to Leeds



The Author on his 7-9 h.p. Baddeley-Peugeot.

1,700 Miles on a 7 h.p. Twin.—

should be studiously ignored, and, proceeding through Ilkley and Otley, the rider finds himself at Harewood, then Collingham, and in about a couple of miles the Great North Road or Leeming Lane is reached. It is then a direct run south through Aberford, Doncaster, and Grantham, to London.—Ed.].

The M.C.C. London-Land's End-London Run.

Next day (Friday) I get all cleaned up, change the tyres, and with my brother ride over, in the evening, to Hounslow, where we put up for the night. Saturday (July 31st) sees us up at an unearthly hour, and at 4.14 a.m. we start on the first stage of the Motor Cycling Club's London to Land's End and back ride. Of the journey down I will say but little. The machine ran like a clock; all the hills were taken on less than half throttle with a 3½ to 1 gear. But something went wrong with my internal economy, and I atoned for my past life, or at least some part of it, on two sodas and milk, which constituted my entire personal consumption during the run to Land's End and thence to Penzance. On Sunday the M.C.C. party go over to Land's End in a 4 h.p. brake. On Monday I try the machine at 4.45 a.m., and it fires splendidly in both cylinders. At 5.2 a.m. Timekeeper Bidlake gives me the word to go on the return journey, and I arrive at Redruth in front of my schedule, so wait a short time. Three miles further on I lose the way, and waste much precious time before getting on to the right road. I am endeavouring to make up lost time when the engine stops suddenly. I suspect the magneto, examine it, see nothing amiss, and try again. No go! Hugh Gibson comes along, stays as long as possible and does his best, but not a single explosion rewards us. I take the magneto down, clean well with petrol, and re-time it, but nothing happens. So there is nothing for it but to wait till a friendly car comes along, and I get a tow into Truro. I suppose it was necessary for that car to go along at thirty miles an hour, and of course the fact that my poor arm was pulling over 300 lbs. of dead weight did not matter, except to me. Off came the magneto, and by noon it was on its way to London, while I went back to Penzance to wait for it. The trouble was traced to the condenser, and it was cold comfort for me to realise later that I might have been able to finish had I thought of cutting the condenser out altogether. A piece of indiarubber under the spring that holds the contact breaker cover on would have done the trick.

Lyme Regis from the Copse.

Awaiting the Magneto.

I filled in two and a half days very well, visiting the Scilly Isles one day and Falmouth the next by sea. On Wednesday, August 4th, the magneto arrived, and

King's Parade, Dawlish.

1,700 Miles on a 7 h.p. Twin.—

on Thursday I trained back to Truro, fitted it on, and at 2 p.m. struck out for St. Austell, Liskeard, Saltash, and Devonport. Here I was confronted with a steep hill on leaving the ferry, and found a difficulty in starting, but I managed to get going up a side turning, and rode through Plymouth without a stop—only to find I had taken the wrong road. However, I had plenty of time, so why should I worry? I went on to Tavistock, Prince Town, Two Bridges, and to Postbridge. At Moreton Hampstead I struck a hill which demonstrated one advantage of a high powered twin. The gradient was severe and the corners awful: I found I could climb well enough with a fairly rich mixture and spark fully retarded, the engine pulling comfortably at slow speed; at the bends I had to nearly shut the throttle, but once round I could slam the spark forward, the engine would begin to race, and the belt, of course, to slip on the engine pulley. Then by gradually retarding the spark the slower engine speed caused belt to grip, and so to the next corner. At Farrant's Hill my back tyre went down, and while repairing I chatted with a local farmer, who advised me to turn and go to Torquay. I went, but it meant climbing Doccombe, which has bits of 1 in 9, 1 in 8, and 1 in 11. Hereabouts I struck a flock of sheep on a long hill, and this meant riding back down the hill, a long wait, and then another dash for it. My gear was still 3½ to 1. Just before reaching Moreton Hampstead on my return journey I turned off sharp to the left, making for Bovey Tracey. At Newton Abbot I filled up with petrol, lit the lamp, and reached Torquay in good time for supper and a walk round the town. The roads were splendid on this day's run, but very hilly. Troubles (apart from magneto), one puncture and one inner tube chafed through at the butted end.

Carn Brea, Redruth.

Under a Blazing Sun.

On Friday morning, August 6th, I start away from Torquay at eleven o'clock, and make for Teignmouth and Dawlish under a blazing sun, which tempts me to leave the machine at the side of the road while I indulge in a swim. Then alongside the River Exe and across to Topsham. At one o'clock I arrive at Exmouth and have another swim, in the sea this time, after that lunch, and then Sidmouth is my next place of call. Now the collar work begins, and before riding up through White Cross, Newton Poppleton, and Sidford I had to open out the adjustable pulley, so that I could race the engine round the bends, and retard the magneto in order to enable the belt to grip on the level. I ran down into Colyford, and thence to Heathfield Cross and Lyme Regis, the engine pulling splendidly, although the heat was scorching. On to Bridport, Dorchester (where I bought petrol), and

Tropical Torquay from Waldon Hill.

1,700 Miles on a 7 h.p. Twin.—

to Bere Regis. In the churchyard here Tess, the heroine of Hardy's famous novel, is supposed to have set up the family four-poster and put her young brothers and sisters to bed. Thence by Wimborne Minster and Ringwood to Southampton, where I stayed the night.

On Saturday I started at 9.30 for home, travelling by Winchester, Alton, Farnham, Bagshot, Staines, West Drayton, Pinner, Barnet, Enfield to Chingford, arriving at 3.30 p.m. No troubles beyond those already recorded; and I had not touched belt or valves.

On Friday I start on my journey north at 2.30, and by evening reach Newark, where I stay the night. Saturday's journey is to Doncaster, Leeds, and over the route by which I came south. In Leeds I stayed with friends for four hours, and I finished up for the night at Kendal. Next day (Sunday) took me through Kendal, Windermere, Ambleside, Derwentwater, Keswick, Penrith, and Carlisle, and back to Glasgow—in all a total of 1,705 miles. Except for the magneto failure, which is quite an unusual occurrence, the only trouble was as stated—one puncture and one chafed butted tube.

Falmouth Bay.

Private Owners, Trade Riders, and Professionals in America.

THE following extracts from the rules of the Federation of American Motor Cyclists, which were founded on the A.C.U. Competition Rules, may interest our readers:

"Three classes of competitors shall be recognised—private owners, trade riders, and professionals.

"A private owner is an amateur who, since the adoption of these rules, has never engaged in motor cycle competition or exhibition as a trade rider; who actually owns the motor cycle used in competition; who is not connected in any way, either directly or indirectly, with any person or firm that manufactures, assembles, sells, or repairs motor cycles, motor vehicles, or internal-combustion engines, or who operates them as a trade or profession; who has never received, either directly or indirectly, any compensation whatsoever for engaging in motor cycle competition or exhibition; who has never knowingly competed in any sport against a professional; or who has never sold or otherwise realised pecuniary benefit from a prize.

"A trade rider is an amateur who is connected, either directly or indirectly, with a person or firm that manufactures, assembles, sells, or repairs motor cycles, motor vehicles, or internal-combustion engines, or who operates them as a trade or profession; who has never competed for cash, either in the form of prizes, wagers, gate receipts, or appearance money; who has never knowingly competed in any sport against a professional; who has never sold or otherwise realised pecuniary benefit from a prize; or who for any other reason is not eligible as a private owner.

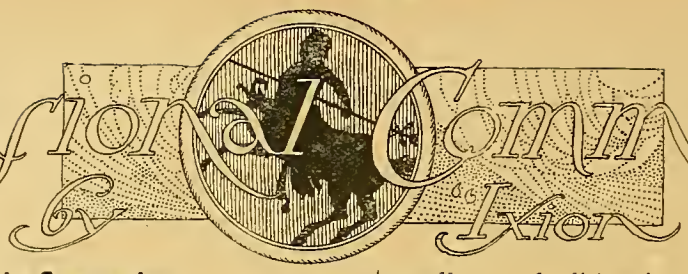
"A professional is one who has competed for cash, or who has otherwise violated the above rules applying to a private owner or a trade rider.

"A trade rider who has severed all connection with the trade, and who for six months previous to his application for reinstatement has had no connection, either directly or indirectly, with the trade, may be placed in the private owner class by unanimous vote of the Competition Committee."

Easter falling earlier this year, it behoves readers who already possess motor cycles and require them overhauled before the holidays to lose no time in placing them in the hands of the makers. There is usually a big rush during the four weeks preceding Easter, so that now is the time to have repairs promptly and efficiently executed. The foregoing is the gist of a reminder to hand from the N.S.U. Motor Co., Ltd.

AII

Occasional Comment



Riding in Spectacles.

Dr. Mevan, of Blaina, Mon., has forwarded to me samples of a special goggle he has patented for use by spectacled motorists. The miseries of a spectacled driver face to face with a long journey on a wet night can obviously be better imagined than described. The patent goggle has no glasses, and consists simply of two short tubes of clear celluloid fitting in a frame which lies closely against the wearer's face. It acts in two ways. The depth of the tubes (3in. measured on the side near the ear) makes them act as miniature weather screens with regard to the optical spectacles, worn underneath them, so that in any case very little rain or snow could be blown on to the lenses. Secondly, if the goggle is padded to fit closely to the face, a cushion of air is interposed between the eyes and the tubes, and protects both eyes and spectacles from draughts and rain.

The 1910 End-to-end Trial.

I have just received a long letter from a well-known medal winner in the A.C.U. Six Days' Trials, who hopes that hill-climbing will receive greater prominence than in previous End-to-end runs, and that marks will be awarded as last year. In 1909 the riders were observed (in my opinion rather imperfectly) on three or four stated hills, for climbing which marks were allotted. Riders who failed to obtain a high percentage of marks on the official hills were thereby disqualified from obtaining a gold medal, no matter how regular their running on the flat might be. This is a splendid system, but the End-to-end course does not contain a single ascent to compare with Wenlock, Festiniog, Dinas Mawddwy, and Birdlip. Redhill is nothing, Shap is nothing, and the northward side of Berriedale is merely awkward without being really steep. The 1909 system of hill-climbing marks as applied to the original End-to-end course would be a delusion and a sham, and would simply lead to a few riders losing marks on Berriedale because they had never seen it before. It is a fluke ascent at the first time of asking. I am therefore very glad to say that the 1910 End-to-end is to supply a real criterion of hill-climbing powers. The riders are required to make the ascent of Amulree—one of the most difficult climbs I know, which no badly handled machine can ever manage, and it is beyond the compass of any engine that has lost tune. It is of great length, cannot be rushed, owing to awkward turns, has a poorish surface, and is exposed to gales. When man and machine are growing a trifle weary of it they have to negotiate an infamous double hairpin bend, and above the bend are some 600 yards of sufficiently exacting gradient. This climb will hall mark the good machines in the trial. Stiff as it is, it is not in my opinion one whit too severe a task. If a new engine driven by an expert cannot climb Amulree, a well-worn duplicate is no fit mount for a touring amateur. The preliminary announcement states that the competitors are to tackle the northern side of Amulree. I sincerely hope this is a clerical error. The southern side, approached from Sma' Glen, is more suitable.

Silencers in the T.T. Race.

The original regulation that silencers should be dispensed with in the actual T.T. race, though not in practice, was sound, because it is almost impossible to enforce a uniform standard of silence. At the same time I am very glad that silencers are to be enforced, because several riders are often close on each other's heels near some of the difficult corners, and if by reason of the noise made by an open exhaust each rider is deaf to the proximity of others, accidents are extremely likely to result. Last year I saw several episodes both at Ballacraine, Glen Helen, and the Devil's Elbow, which confirm this opinion. As silencers are compulsory, some means might be taken for reducing them to a common denomination of silence or its absence. Is it too much to hope that some public-spirited technical expert would volunteer to make tests before the race? If a gentleman with the requisite qualifications could be found, it would be very simple to make each entrant send in the silencer he proposes to use a month before the race. The technician could test these silencers on a bench engine, and fake them towards a tolerable uniformity. They could then be served out on the morning of the race, and substituted for the silencers used in practice, under the eye of official observers. Perhaps the ruling does not deserve so much trouble; but as a matter of fact we are all rather in the dark as to exactly how much efficiency is gained by using a very make-shift silencer. It would be interesting if some fully qualified technical expert would take a standard silencer off some well-known machine, and see what percentage of efficiency he could obtain by removing its entrails and drilling out its end plates. Some T.T. silencers last year were like the Irishman's coat—a mass of holes held together by stitches.

The pocket electric flash lamp which was mentioned in *The Motor Cycle* of the 10th inst. is now ready for delivery, and the makers, Priest and Co., 66, Bishop Street, Birmingham, have kindly sent us one of the first of these lamps, which is an extremely neat production. The lamp and accumulator battery are enclosed in a nickel-plated case, the switch being so constructed that the light can be left on continuously if desired. Either .8 or .4 amp. Osram lamps are fitted, but although the .8 amp lamps give greater light the makers prefer to fit the smaller capacity bulb, which enables the accumulator to retain its charge for a longer period.

BENZOL AS A FUEL.

The Origin of Benzol, its Constitution and Use.

BY J. BELLERBY.

WHEN the general public are offered something which is claimed to be very much better—and yet cheaper—than a standard article, they are apt to be dubious and exclaim, "No thanks. I've heard that tale before!" The motoring section of the public are no exceptions to the general rule, and at one time could not believe when offered benzol at a low price that it was at all likely to ever equal or supersede petrol.

Now benzol is not a patent medicine, or even a patent fuel, but, on the other hand, is the basis of a very large industry, viz., the making of dyes, explosives, medicines, disinfectants, and perfumes, to mention a few of its uses, and for years the supply was not equal to the demand from the dye trade alone. When petrol engines were first introduced the users could not afford the price for benzol (which was 15s. per gallon at that time), and in their search for a substitute found a valuable fuel in petrol, which prior to that time was a drug on the market.

However, during the intervening period, a greatly increased supply of benzol and a smaller demand from

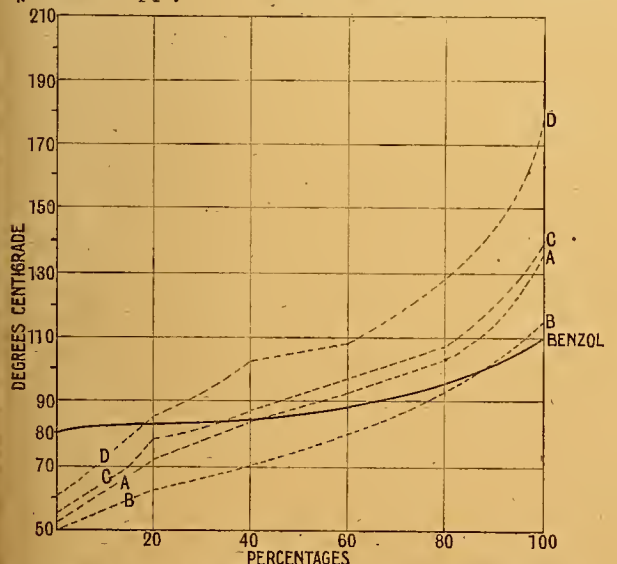


Diagram of curves, showing the volatility of various petrols compared with ordinary benzol. A. Pratt's Perfection. B. Pratt's special. C. Shell. D. P.G.R. Broad line 90% benzol.

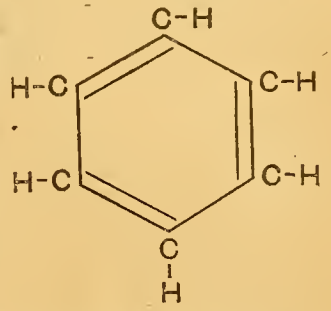
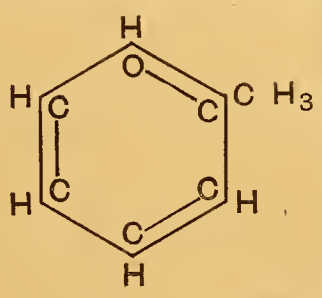
the dye trade have created a surplus which has been placed at the disposal of motorists at a very much lower price than petrol.

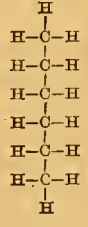
When coal is heated strongly and the air excluded, coke, gas, and a little tar are obtained, and this is done on a very large scale in gasworks and coke ovens. In gasworks practice, the main object is the making of gas for lighting purposes, so no benzol is available from that source, except the small percentage in the tar. In coke oven practice, coke is the principal product, and the gas is used to heat the ovens, but before being used for this purpose it is washed with, firstly water which extracts ammonia, and then with oil, which absorbs the benzol present in the gas. This oil is next heated, when the benzol distils off and is collected and very carefully refined with chemicals and then redistilled and fractionated into the various commercial fractions, the first fraction being benzol.



Benzol is a compound of carbon and hydrogen of the formula C_6H_6 represented graphically as a hexagon in which all the carbon atoms are bonded together, making a closed ring.

Its specific gravity is .884, and boiling point 80° C. Commercial 90% benzol contains another body called toluol C_7H_8, that is a combination of benzol and marsh gas, CH_4. Its specific gravity is .875, and boils at 110½° C. Commercial benzol (*i.e.*, 90%) has specific gravity .882, boils at 82° C., and shows 90% at 100° C., dry at 110° C.; its calorific value is 10,000 K. Petrol consists of a number of hydrocarbons of another series, in which the molecules are represented as chain:—





of which Hexane C_6H_{14}, Heptane C_7H_{16}, Octane C_8H_{18} are the principal bodies found in petrol. Its specific gravity is .700 (approximately), and it boils at 60-70° C., and shows 65-70% at 100° C., and dry about 150° C.; its calorific value is 11,200 K.

As a modern engine is essentially a heat engine, the calorific value is a good index as to the value of a fuel, and, comparing benzol with petrol, we find one gallon of benzol contains 8.8 × 10,000 = 88,000 K.; one gallon of petrol contains 7 × 11,200 = 78,400 K.—an advantage in favour of benzol of 9,600 K. As benzol contains 1.8 lbs. more to the gallon than petrol, this is at an equal price; but when we compare them at to-day's price we have:

$$\text{Benzol } \frac{88{,}000}{7} = 12{,}555 \text{ K. for 1d.}$$

$$\text{Petrol } \frac{78{,}400}{15} = 5{,}226 \text{ K. for 1d.}$$

Which speaks for itself.

Benzol as a Fuel.—

As will be seen from the boiling points, benzol has really a lower average volatility than petrol, and is therefore more easily gasified completely than petrol, and so perfect combustion is more easily obtained. From this it follows that deposits on the piston head, cylinder, and valves should be of less frequency with benzol than with petrol, always, of course, taking into consideration that deposits are mainly caused by the lubricating oil being charred.

In using benzol for car and motor cycle engines two things must be watched in particular, namely, that plenty of air is admitted (or, in other words, less benzol sprayed than petrol would be normally), and, if necessary, to weight the float with a blob of solder or a washer slipped over the needle, as, having such a greater gravity than petrol, the float rises higher in the liquid, and so the needle valve closes earlier, and the height of fuel in the jet is below the normal. A low level makes starting difficult and slow running impossible. Some carburetters, such as the B.B. and Triumph, do not require any alteration whatever when using benzol, and all that is needful with these is to open the extra air inlet more than when using petrol.

THE PROBLEM OF THE PRIVATE OWNER.

Summary of the Discussion on a Paper read by the Rev. P. W. Bischoff before the A.C.U. (see page 45 last week.

IN opening the discussion the chairman, Mr. Harry J. Swindley, said they were grateful to Mr. Bischoff for his interesting and painstaking paper, which was open for discussion, and Mr. Bischoff would like a vote taken upon the scheme as a whole.

The lecturer's proposed solution of the problem was briefly that the definition of an amateur be as follows:

1. An amateur is one who is not engaged for pecuniary gain, directly or indirectly, in the motor or allied trades, nor in this or in any other sport.
2. Who is not assisted financially or otherwise, directly or indirectly, by any person engaged in the motor or allied trades.
3. Who has not competed for a declared wager or staked bet, nor, except in track races for special racing machines, for a money prize.
4. Who has not taken part in any competition held not under the Amateur Code of the Auto Cycle Union.

That an intermediate class be formed, to be known as "expert competitors," who are assisted by the trade, but do not engage in this or any other sport for pecuniary gain, and in all other respects conform to the definition of an amateur.

That those competitors who do not conform to either of these definitions be called professionals.

Mr. W. H. Wells said he was afraid, unless the A.C.U. was able to adopt a very strong attitude as regards amateurs, they would have the same thing in connection with motor cycling as had been experienced in connection with cycling. Manufacturers were far more desirous of having events won by amateurs than by the professional or trade rider, and made special efforts to secure such wins. He was in the trade and liked to compete occasionally, but he objected very much to be classed as a professional. If there were a trade riders' class as in America it would enable him to enter, but not as a professional. He was strongly in favour of giving cash prizes to professionals only.

Mr. W. Pratt said so far as he was concerned the paper was somewhat disappointing. It certainly wanted very careful consideration. Mr. Bischoff suggested that there was a falling off in the amateur entries, but looking back at some of the big trials they found the amateur or private owner class well represented. (Hear, hear.) Those were competitions in which the amateur did like to compete with professionals or people engaged in the trade. The pure amateur was a very difficult man to find in the motor cycling world. The definition of the A.C.U. seemed to cover all that was wanted as far as the private owner was concerned.

Mr. F. A. Hardy thanked Mr. Bischoff for having had the pluck to bring the question up. He thought amateurs should have more safeguard offered by the Auto Cycle Union, particularly in the matter of issuing riding licences to those taking part in open competitions. As it would do no harm to have the scheme considered by a body of experts he would move as an amendment "That the A.C.U. Committee be instructed to consider the present position of participants in motor cycle competitions with a view of defining them in two classes, viz., private owners and expert competitors."

Mr. V. Hart said this was the first lecture that he had attended at which the lecturer proposed to take a vote. He asked whether the procedure was in order.

The Chairman, replying to Mr. Hart, said that a vote at that meeting did not bind anyone. If the meeting chose to vote it could do so, and that would stand merely as an expression of opinion of those present.

Mr. H. G. Cove said if Mr. Bischoff's scheme were adopted the only real amateur would be the 'Varsity man with indulgent parents. (Laughter). If manufacturers liked amateurs to win events, was not that an incentive to get young men into the ranks and do the best they could. If a man were supplied with an ordinary stock machine there was no advertisement, but if he were given a picked machine, then he became subsidised. He was against the scheme.

Mr. Hart thought the question lay in a nutshell, and Mr. Cove had put it accurately. The average owner who paid for his machine could not afford to keep a second machine for racing. They all had the greatest respect for Mr. Bischoff, but he could see no reason why they should open the ranks of the A.C.U. to a continuous form of agitation in respect of the amateur or professional when they had gone on quite comfortably up to the present.

Mr. Greisbach said he was always pleased to compete with a trade man. He did not know that the trade man, or the group of well-known riders, had a great advantage over the private owner, provided the private owner had enough intelligence to tune his machine up to the extent of doing its best. He thought that he stood just the same chance in every way. The sham amateur was not of any great value, and he did not see any objection to competing with him.

Mr. J. W. G. Brooker thought it was utterly impracticable to define the amateur on the lines put forward. That was his experience, and he believed everyone present would be of the same opinion. With Mr. Hart, he did not think there was any call at the present time for the proposed definition of the amateur.

The Rev. P. W. Bischoff, in reply, said a great deal of pressure had been brought upon him to write another paper, and he had said that one thing had impressed him, and that he would be prepared to deal with it. He knew in taking up the question at all that he laid himself open to criticism. It was, of course, a difficult problem. It had been said that he had adopted a wrong line of suggestion. As a member of the A.C.U. Council and of the Executive Committee, he wished to say that in all things he identified himself with that body. He did not suggest that that meeting could adopt the suggestions with any force; it had no executive authority, but its opinion had weight everywhere. Mr. Pratt said there was no falling off in entries for the big events; he had never said there was, but in the local clubs (and he had been all over England) he heard the same story—local secretaries cut down the classes because they could not be filled up. Mr. Cove objected to the subsidised amateur; so did he, but the thing existed. His answer to Mr. Hart's suggestion to let well alone was that things are not well, and he would much rather see things better.

The Chairman intimated that Mr. Bischoff would not press his resolutions.

Mr. Bischoff said he would have liked a show of hands.

The following amendment, in addition to that moved by Mr. Hardy, was handed up by Mr. Hart, seconded by Mr. Pratt: "That this meeting refuses to vote upon matters upon which no prior information has been offered." This amendment upon being put to the meeting was declared carried, and the other motions accordingly dropped.

THE WINTER OVERHAUL.

By B. H. DAVIES.

FROM now onwards motor cycling may become increasingly enjoyable, as the days lengthen out, and the temperature fitfully aspires towards a summer which meteorologists tell us is going to be another Diamond Jubilee. Consequently the rider who is not to be blessed with a new mount for 1910 should seize on the first warm day or the nearest warm shed to overhaul his old jigger as thoroughly as possible. No doubt the goldbugs will give a lordly order to the local garage to send up for the machine and return it within two days fit for a record breaking spin on Brooklands; but the needy owner who has to do his own dirty work need not envy his plutocratic brethren. For one thing his overhaul will be the better of the two, since in this vale of tears "he worketh best who worketh for himself," and also he will gain such a novel insight into the whimsies of his machine that roadside troubles will be shorn of half their terrors for the honourable spell of roadwork that lies ahead.

The Engine.

The engine is at once the most important and the most difficult item to tune. It need not be removed from the frame, but the cylinder and timing gear should be removed. Test the cylinder for wear with a pair of callipers—wear is most pronounced towards the top of the piston stroke. If the wear be excessive, send the entire engine to a good firm who make a speciality of reboring. Otherwise merely fit new rings supposing the compression is weakish with the old ones. "Hints and Tips for Motor Cyclists" gives very full details *re* overhauling the rings. Remove both valves, test the stems for truth, inspect the exhaust velve's neck for threats of breakage, and grind in both valves. Scrap the old valve springs, and fit new ones, also new cotters to the valves, and file any burred edges off the cotter slots. Scrape the surface of the joints between cylinder head and valve-caps quite clean, and fit new washers, as also to the compression tap. Remove every trace of carbon deposit from piston and cylinder heads—a long job, but quite simple with a long bladed screwdriver, and worth doing well. Next look for wear in other vital parts—all bearings and the valve cams. The least token of wear in the valve cams or rockers makes new parts advisable and they do not cost much. If the valve gear is of the cheap order, cams and pinions being assembled with pins or keys and nuts, instead of being machined from the solid, examine these fastenings very jealously indeed; nothing is more likely to give serious trouble in the second year of use. Wear in the connecting rod and crankshaft bearings is not really very serious until it makes itself audible, and a second season machine will seldom require attention here, unless it has been very badly used. The bushes of the timing gear bearings are more likely to be worn, and any garage will replace them quite cheaply, especially if the assembling, etc., be done by the owner. New bushes, including fitting, only cost a shilling or two; and these can usually be supplied by a local engineering shop. The crankcase should be thoroughly cleaned out with paraffin, to remove oil sediment, especially from the narrow oilways, if there are any. I first drain my crankcase of all lubricant, then let it soak in paraffin for a few hours, and finally reassemble the engine, and get rid of the paraffin by pedalling with the drain tap open; to conclude, inject two or three charges of fresh oil, and pedal this well into the engine on the stand, before allowing the engine to run under its own power.

The Ignition.

If the ignition be coil and accumulator, a new brass for the contact breaker bearing, new platina for the contacts, and a new spring contact blade, are the most probable replacements which caution will advise. The wiring should be thoroughly overhauled, any wires showing excessive flexibility or worn covering being renewed. The insulation and packing of the accumulator box may be made sound and workmanlike by seccotining rubber sheets on its sides, and all sharp orifices through which wires pass should be similarly protected with rubber, or, better still, if ebonite bushes can be procured to fit the holes they will prevent all chafing. If the ignition is by magneto, the instrument may be carefully overhauled according to directions in the makers' handbook; but if it is suspected that the magneto has seriously lost efficiency, it should be returned to the makers, who will overhaul and test it for a few shillings, apart from the cost of large replacements. As a rule, it is ample to clean out the oil reservoirs, polish and adjust the contacts, test the cam for wear, verify and adjust the timing, after which the magneto should be just as efficient as when it was new.

Carburetter.

Probably a good adjustment of the jet, air adapter, and air intakes has been arrived at during the previous year, affording moderate economy of fuel and high efficiency. If so, it will be enough to clean the entire device thoroughly, examine the wires to the handle-bar control for threats of breakage, test the petrol level, and see that the cut off needle valve is petrol tight. The petrol pipe should also be examined for cleanliness and signs of leakage.

The Cycle Frame.

I make it a rule, when my machines are stripped for overhauling, to take a short run by night, using the stripped frame as a pedal cycle, using either the crankcase (empty) or a stout wood block as a connecting link for the gap left by the removal of the engine. Under these conditions I often discover little things amiss with the cycle part. If an owner does not care to face so much trouble, he should at least remove the front fork from the steering head and overhaul the bearings very carefully indeed, as owing to various causes, among which is insufficient provision for regular oiling, this particular bearing is very apt to wear faster than is desirable.

In addition he should remove and examine the cones from both hub spindles. If the cones are chipped or worn they should be replaced; in re-assembling the bearings, if any difficulty is experienced the balls are easily held in place with the aid of motor grease or vaseline, while the cones or cups are screwed up. All these cycle frame bearings should be filled with

The Winter Overhaul.—

thick oil or thin grease, and carefully readjusted, the adjustments being scrupulously locked up afterwards at a quarter of a turn less than dead tight. A good guide to correct adjustment of wheel bearings is that when revolved slowly the wheel should always stop with tyre valve at the lowest point of the revolution, without the bearing showing any sign of play when wheel is held by the rim and shaken sideways. The brakes must not be forgotten, examination of all joints, whether at wire nipples or by bolt, nut, and split pin, being particularly thorough, and the shoes receiving attention in addition. The free-wheel should not be meddled with by an unskilled owner. If it has given no serious trouble previously, it will be sufficient to swill it out very freely with paraffin, make sure that all the pawls are acting with strength and certainty, and then refill it with good cycle bearing oil. The pedalling chain will want thoroughly cleansing, and if desired it may be removed, slightly heated, and plunged into a bath of melted tallow. It is unlikely to require renewing unless it has been fitted to a machine which required constant pedal assistance.

The Tyres.

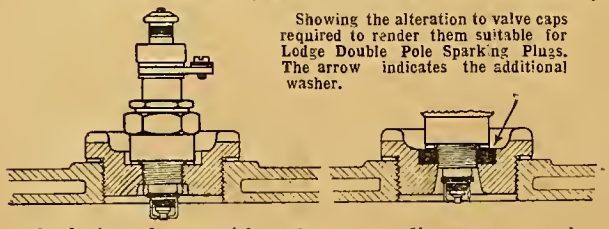
The tyres will probably be content with a single renewal, namely, fresh valve rubbers to both valves. But apart from renewals, the tyres and rims are likely to require very close attention. The inside of the rims will have to be enamelled. The tubes will have to be tested for retaining air; some riders leave tiny gradual leaks over till summer comes, but it is an awful nuisance to waste fine weather in overhauling tyres, and the best plan is to take both wheels out of the forks, carry them up to an attic, and get them into perfect order in comfort and indoors. I begin by removing both tyres, and painting the inside of the rims with black enamel, pushing the brush well under the beaded edges; while the enamel is drying I go over the tubes, and generally find a dubious patch or two; these are half pulled off, half melted off with naphtha, and remade. When both tubes are so thoroughly airtight that they will remain fully inflated for several days at least, the inside of the covers next receive attention. Generally a broken thread or two has been left sticking up out of the fabric where small nail punctures have occurred. These will chafe the tube in time, and besides they mark the presence of small holes by which water enters. The projecting thread is cut off, and a very smooth rubbered canvas patch with rounded corners solutioned over the hole. The tyres then go back on the rims, and are blown up board hard, after which a search for cuts commences. Dozens of tiny cuts are quickly found, but I do not trouble myself about small cuts which have not gone right down to the fabric; it no doubt pays to doctor them with tyre stopping, but it is a wearying job, and they are not immediately dangerous. Big cuts are carefully cleaned and filled, a process which is never satisfactory when conducted in a hurry, but which prolongs the life of a cover considerably, when the filling is given several days to dry. I find that if the cut is thoroughly clean, and the stopping is jammed well in with a wood match, it will be almost an integral part of the cover seven days afterwards.

Details.

Some riders are very fond of re-enamelling their frames during the winter. I am not a great believer in the idea. It is astonishingly difficult to produce a good surface by brushwork, particularly if the frame is not stoved afterwards; and very few amateurs have a dustless room to work in. Very fair results may be obtained with some enamels if the old enamel is scrupulously scraped off before applying the new, but if the machine is disgracefully shabby, and the owner has a little money to spare, it is well worth while to strip the frame and send it to a professional enameller. The work of overhauling may be completed by improving the attachment of any accessories which were apt previously to work loose, and by relentlessly scrapping all worn nuts and bolts, including the retapping or screwing of any threads which have worn or partially stripped. When the overhauled machine is taken on the road for the first time, it will seldom prove to be perfect. If the compression is disappointing, do not trouble until the engine has run about a hundred miles; but if other details are faulty, a very few minutes spent on readjustments of timing, ignition, or carburetter, will generally make the rider feel extremely pleased that he elected to perform his own overhaul.

DOUBLE POLE SPARKING PLUGS.

IN a recent issue of *The Motor Cycle* we pointed out that Lodge double pole plugs will not fit all makes of engines until the valve caps are altered, owing to the fact that the electrodes project too far into the valve chamber, and the valve heads are likely

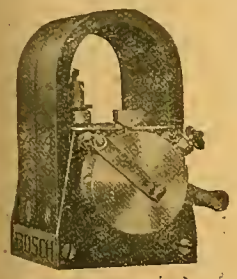


Showing the alteration to valve caps required to render them suitable for Lodge Double Pole Sparking Plugs. The arrow indicates the additional washer.

to foul the plugs, with, of course, disastrous results. Lodge Bros. and Co., Birmingham, informed us that the alteration to the valve caps meant fitting a washer to the cap which prevented the electrodes projecting too far. To enable us to make the alteration quite clear to our readers, we reproduce herewith two sketches, one showing the Lodge plug fitted to an ordinary valve cap and the other the same plug screwed into a valve cap with packing washer to reduce the reach of the points. At first sight one would be inclined to think that the introduction of washers to the valve caps would lower the compression appreciably, but such is not the case. The slight clearance around the sparking points tends to enlarge the compression space a little, but this is balanced by the volume of the plug projecting into the cylinder, thus leaving the compression the same. When these double pole plugs are fitted to an ordinary single-cylinder motor cycle engine with side by side mechanically operated valves it is usual to fit one plug over the inlet and one over the exhaust valve. With automatic inlet valves an extra plug hole must be made.

THE NEW BALL-BEARING BOSCH MAGNETO.

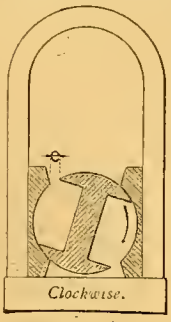
FREQUENT references have been made to the new ball bearing Bosch magneto, but hitherto no illustration and particulars of it have appeared. The DA2 ball bearing pattern is now being delivered to buyers of new models, consequently readers would like to know wherein the new magneto differs from last year's type. It is only in detail that alteration is noticeable, the main features remain as before, and, indeed, it would be difficult to improve upon such a wonderfully reliable piece of ignition apparatus. The outward appearance of the contact breaker end has been changed, the spring holding the cover in position swinging from the side, this being on account of the condenser (17) having been moved from over the armature to immediately behind the contact breaker. The condenser now revolves with the armature.

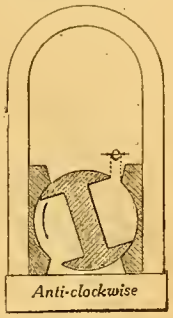


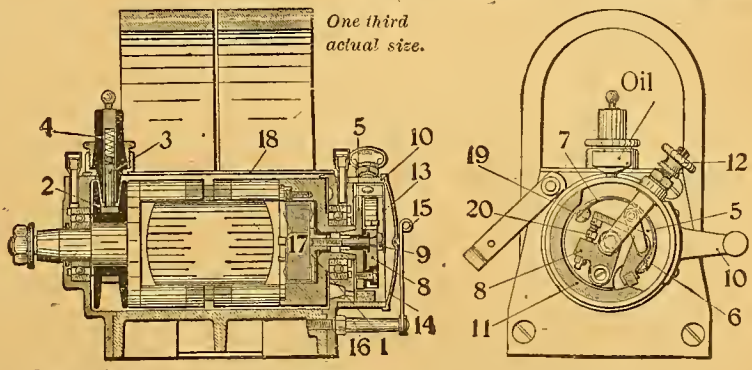
How to Time the Magneto Spark.

The dust cover plate (18) over the armature is readily removable on the new model, and this greatly facilitates the timing of the engine, as the armature is exposed, and its position can be noted. It is well known that the current generated in the winding of the rotating armature reaches a maximum twice during each revolution, only one of which is used for effecting a spark in the case of a single-cylinder engine. To time the magneto the makers recommend the following method: Bring the piston exactly to the top of compression stroke—that is, with the exhaust valve closed—and mark this position on the engine pulley, making a corresponding mark on the crank case. Now give the engine one complete turn forward, bringing the two marks together again, when the piston will be in the required position. Remove dust cover 18, but care should be taken not to damage carbon 3; then bring the armature by hand in position as shown in the sketch, seen from the driving end rotating to the right or left. The distance marked *c* on the sketch should be 5 mm. Finally, tighten the chain wheel on the cone, care being taken not to move the armature.

The switch terminal on the new Bosch is placed in a more convenient position, and improved oiling arrangements are provided. A new type of h.t. terminal which is unaffected by wet is being supplied with the later models. The steel segment is retained as well as adjustable contacts, so that the only part likely to require renewal, and that after several thousand miles, is the fibre insertion at the end of the bell crank lever. The timing lever on the new model is all complete, consisting of brass ring and arm, short circuit clamp, and segment for make and break. It permits of a variation in the advance of 25° measured on the armature spindle. This is equal to 50° on the crankshaft, as the armature rotates at camshaft speed.







1. Contact plate.
2. Slip ring with distributor segement.
3. Carbon.
4. Carbon holder.
5. Contact breaker disc.
6. Bell crank lever.
7. Bell crank lever spring.
8. Contact piece.
9. Fastening screw for contact breaker.
10. Timing lever.
11. Steel segment.
12. Short-circuiting screw.
13. Flat spring for timing lever.
14. Brass end cap.
15. Flat spring.
16. Bolt for spring 15.
17. Condenser.
18. Dust cover.
19. Short platinum screw.
20. Long platinum screw.

Various improvements have been made recently in regard to the Dall belt fastener. Among these are the following: The nut for the screw is provided with a square which fits into a square hole in the top plate, so preventing the nut from turning. Indentations have been made in the top and bottom plate to enable them to sink into the leather or rubber of which the belt is composed when the jaws are pinched together. The bottom plate is turned downwards to prevent it cutting the belt when the leather passes over the small diameter engine pulley. To vary the length of the belt when using an adjustable pulley, the Dall connecting link will be found useful. It will be noticed that this link enables a short section of the V belting to be fitted in the centre by means of the single screw provided. The patentee has certainly devoted much thought to make his ingenious fastener handy and readily adjustable as to length.

Paragraph No. 331 in "Hints and Tip for Motor Cyclists," published on the 10th inst., mentioned that a few of the Amac carburetters appear to have been sent out with throttle springs that are not quite strong enough to keep the throttle valve down on its seat against the fierce suction of a good engine. Will readers kindly note that this paragraph only refers to the 1909 pattern of carburetter?

A selection of questions of general interest received from readers and our replies thereto. All queries should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, E.C., and whether intended for publication or not, **must be accompanied by a stamped addressed envelope for reply.**

Sending Accumulators by Rail.

I wish to send some accumulators a long railway journey. They are in use at present. Kindly tell me how I should pack them? Should the acid be emptied out, or will this injure them in any way?—W.A.W.

The best thing to do will be to empty all the acid out of the accumulators, let them dry, and then send them packed in a box to their destination. When they arrive they should be refilled with acid, and would then be ready for use again after being placed on charge for a short time.

Calculating Gear Ratio. Fitting an Adjustable Pulley.

Please tell me (1) How to calculate the gear of a belt-driven motor cycle, and (2) if you think a novice (like myself) could fit an adjustable pulley?—H.S.

(1.) To calculate the gear is a simple matter. Mark both pulleys, put on the belt, raise the exhaust lifter, and count how many times the engine pulley revolves to one revolution of the rear pulley. (2.) It would be better for you to get an experienced man to fit the pulley, as unless you have had some experience in engineering it would be difficult to cut the keyways, fit the key, etc.

Using the Spark Lever for Controlling Speed.

On my old accumulator cycle I used to cut down the gas, setting the air to match, as much as possible, and regulate my speed by means of advancing and retarding the spark. I am getting a new magneto motor cycle, and am told that I shall have to drive by the throttle and air only, and must not regulate speed by advancing or retarding the spark. Kindly explain this, and tell me why it is?—R. C. S.

The advice given to you is quite correct. The range of advance and retard of the magneto is less than is the case with a machine fitted with accumulator ignition; consequently it is best to keep the spark lever well forward, and to regulate speed by the throttle and air levers. The magneto spark has the advantage of advancing and retarding itself automatically, since it increases in intensity in proportion to the speed of the engine.

Motor Cycle v. Racehorse.

Kindly give me your opinion with regard to a match against a racehorse under the following conditions: The race to be run on Epsom racecourse, Metropolitan course 2¼ miles, the motor cyclist receiving a flying start. I shall be riding a 1909 3½ h.p. T.T. Triumph. The gentleman riding the horse weighs about thirteen stones. The match to be for £100 aside. Conditions—weather favourable and turf holding. I should be interested to see the comments of your readers.—L. E. SKERTCHLY.

The race would certainly be an interesting one, and no doubt hundreds of our readers would like to have an opportunity of seeing it. Provided the ground is firm, the motor bicycle should easily beat the horse with a flying start. Your machine should be capable of nearly a mile a minute on a track, whereas the fastest racehorse has not exceeded thirty-five miles per hour for a mile.

Multi or Single-point Sparking Plugs.

For some considerable time my 1909 Triumph has been very refractory at slow speeds, misfiring setting in below about ten miles per hour. The carburetter received every attention, as also did the contact breaker, the points of which I set to give various breaks, but all with no better results. During my trials to find the cause I used two new multi-point plugs of different well-known makes, but various spark gaps made no difference. I was contemplating having the magneto tested, but on the verge of so doing I came upon an old single point plug of good manufacture, and inserting it into the cylinder, started up with the most excellent results. My machine now starts easier, seems more economical, and lastly runs with the greatest flexibility. Is not this experience opposed to accepted theory?—R.W.C.S.

The experience you have gone through with your machine is quite interesting. It certainly seems to favour a single point plug, though personally we have not been able to detect any difference in the running with either type.

Postman Hadlow with his mail carrier tricar, which he drives twice daily, depositing and collecting mails, between Sittingbourne (Kent) and Frinsted. (See Current Chat pages.)

Improving Engine Speed.

I have a 2½ h.p. lightweight Rex with Bosch magneto and Amac carburetter which runs quite well slowly, but I am anxious to improve speed. Compression is good. I can make engine misfire if air is fully open. If I advance spark too far it will knock. Exhaust valve has ¼in. lift and inlet automatic has ⅜in. It does not run any faster on the stand than on the road. It climbs hills very well. What governs the speed of an engine?—A.J.R.

The exact cause of the trouble is not at once apparent to us. The timing of the magneto seems to be at fault, as the engine should not knock even when the lever is advanced to the full. It may be that the chain wheel on the cone of the armature shaft has come loose. In any case the timing of the spark should receive attention first of all. Knocking is usually due to an excess of carbon deposit. We should recommend you to dismount the cylinder and see if this is your trouble. Engine speed has many governing factors, and if any one important part is wrongly adjusted, the engine speed would suffer. We refer you to "Motor Cycles and How to Manage Them" for a complete answer to your last query.

Respecting Sidecars and Change Speed Gears.

I am about to purchase a 7 h.p. Matchless, and I want a sidecar, as well as a good, cheap, reliable two-speed gear for it. I suppose I could climb most hills without a two-speed gear, but starting and traffic driving would be unpleasant without one, especially with a 12 stone passenger. (1.) Kindly give your opinion of the Millennium two-speed engine-shaft gear. I do not fancy the gears working in the back hub. They seem inaccessible, and put all the weight on the back tyre, and I think it will have enough with our weight—about 24 stones. (2.) How does a castor wheel sidecar behave in grease? Rigid sidecars, I suppose, are the best in that respect? (3.) Is it possible to use a motor bicycle with rigid sidecar when the latter is empty? If not, which is the best type of sidecar? I want one that would not skid.—C. W.

You should certainly climb most hills if a clear straight run were always possible, but, of course, a two-speed gear would be desirable, and practically indispensable on certain occasions. Starting on the low gear would be quite easy. (1.) Engine-shaft gears throw some considerable amount of strain on the engine bearings, which they are not always capable of withstanding. Personally, we should prefer the same make of hub gear with the plate clutch incorporated. This gear is exceedingly well designed, and permits of starting the engine with the pedals, with the back wheel resting on the ground. There is also the gear fitted by the makers of the machine you have selected, which has the same feature. (2.) Not so well as a rigid sidecar; there is nothing apparently to stop it skidding. (3.) Yes, quite possible if care is taken on cambered roads and in rounding corners. It is also possible to sit in the sidecar and drive the bicycle if a clutch and two-speed gear are fitted.

Greater Flexibility Desired.

I recently purchased a motor cycle (85 × 85 mm., twin-cylinder), and I find that it has a rooted objection to going at less than about fourteen miles per hour. It is fitted with J.A.P. automatic carburetter, and, of course, magneto ignition. I have made all the usual adjustments, viz., set the plug points close, raised the level of the petrol in the jet, etc., but the machine is still not sufficiently flexible. I now propose to fit a clutch, and shall be glad to have your advice on this matter. I should also like to hear from any of your readers who have had experience with the Mabon or other disc clutches on powerful machines.—J.E.W.

Your trouble seems to be purely one of incorrect carburetter adjustment, as one of the beauties of a well-balanced twin-cylinder engine is its ability to run slowly and evenly. It is quite possible that the barrel of the throttle may have slipped round, causing a jet or two too many to be uncovered. We should therefore recommend you to examine this portion of the carburetter carefully. Next try some device for restricting the amount of the main air opening, and examine the steel balls which govern the amount of additional air supplied. You could quite well fit a clutch, or, better still, a two speed gear.

A Motor Cycle for Business Purposes.

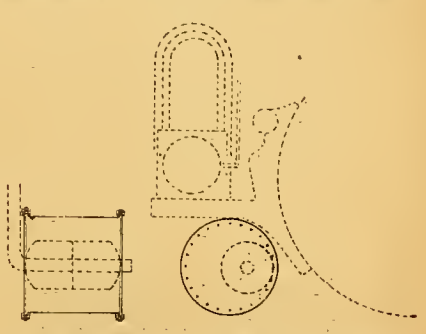
I have a considerable amount of travelling about to do in the counties of Warwickshire, Worcestershire, Staffordshire, and Nottinghamshire. At present I have to go by rail, which, as you well know, is not the most pleasant or least expensive means of transit. I contemplate buying a motor cycle, and should like to know whether you consider I could get a reliable second-hand machine for £20? If so, how about a medium weight machine, say, of 2½ h.p.? Would such a machine take me about in all weathers at a much lower cost of upkeep than the heavier 3½ h.p. machine? Kindly give me an idea of the upkeep of the type of machine you recommend.—W. A., Birmingham.

You should be able to get quite a good second-hand motor bicycle for £20, probably fitted with magneto ignition. Do not purchase a second-hand machine before trying it or seeing it ridden up a fairly steep hill. Yes, a 2½ h.p. machine, if you are not a heavyweight rider, would suit your purpose admirably, but the cost of running would not be much lower than that of a 3½ h.p. You may reckon that the machine will cost about 7s. 6d. per week in upkeep for distances of about 200 miles. The bare running cost, that is, petrol and oil, would not exceed 1s. 9d. per 100 miles.

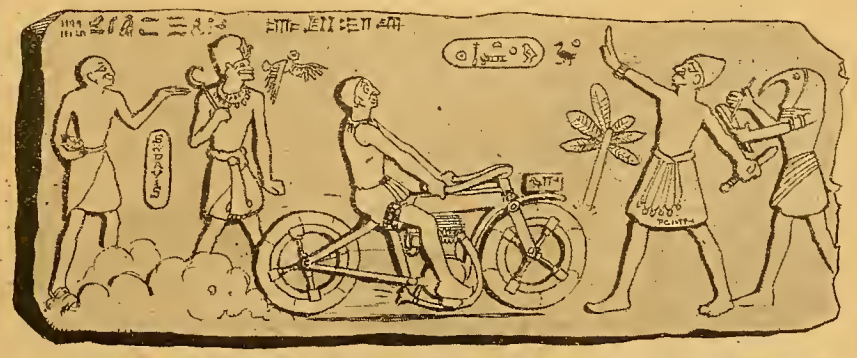
READERS' REPLIES.

Silencer Explosions

I notice in the issue of January 3rd "F. C." wants to know how to prevent popping in the silencer. My Minerva was very bad in that way, but now I have cured it, and at the same time made it one of the most silent machines on the road. All that he needs to do is to fit a larger outer casing to the silencer. I made mine in the following manner: The outer casing consists of a piece of sheet iron rolled



into the form of a sleeve with the ends flanged outwards, and two end plates riveted on. As the bend in the exhaust pipe is so close to the crankcase the holes where the pipe fits in the end plates cannot be in the centre, but must be slightly eccentric, but that will not interfere with efficiency. I enclose a sketch to illustrate my meaning.—H. CAUDWELL.



A recently discovered Egyptian mural carving, time of Rameses II., inscribed in Cuneiform and Hieroglyphic. Ihoth the Ibis-headed God of Time, is evidently supervising an ancient equivalent to a 1910 police trap.

Against Water-cooling.

By "IXION."

I FIND myself in keen opposition to those contributors who have recently pressed for experiments with water-cooling on motor bicycle engines, with a view to its ultimate adoption as a standard detail of our specifications.

A Plausible Case.

At first sight it must be admitted that they have made out a very plausible case in favour of water-cooling. Good as the modern motor bicycle engine undoubtedly is, it certainly suffers from several plain defects, which may be tabulated as follows, even if an absolutely first-class engine be the subject of consideration: (1) Carbonisation of cylinder and piston; (2) breakage of exhaust valves; (3) rapid pitting of exhaust valves; (4) rapid wear of piston rings; (5) liability to knock; (6) liability to overheat; (7) difficulty in starting from cold without petrol or paraffin injections. These defects, I may premise, only manifest themselves after several thousand miles of running (except, of course, No. 7). The advocates of water-cooling contrast bicycle engines with car engines in these seven respects. They prove that these troubles are either wholly absent from car engines, or manifest themselves after a much longer mileage. The car engine is water-cooled; the cycle engine is air-cooled. Water-cool the engine of the motor bicycle and *voila tout!*

A Reminder.

"Rotator" and "Ailette" appear to have forgotten certain experiences which I frequently remember with a stab of pathos. I have already owned two motor bicycle engines which in each of the above seven details were equal to a good motor car engine, and yet were air-cooled. One of them was a 2¾ h.p. M.M.C., the other a 2¾ h.p. De Dion. Neither of these engines ever dreamt of breaking a valve. I ran them both well on into a five figure mileage without ever touching the piston rings. Neither of them ever overheated or knocked till the day I sold it. Neither of them normally required any injection to make it start on the stand or road, if I may except a few occasions in very cold weather when I had been using very thick oils. Neither of them ever dreamt of getting badly carbonised in 2,000 miles, for the simple reason that they were fitted with surface carburetters, which sucked in their air supply at a point where little dust was encountered, and also because a lower compression and less tightly fitting pistons and a lower rate of revolution enabled them to run with far less generous lubrication than the modern engine requires. It is therefore obvious that it is possible to bring the cycle engine to the level of the car engine in these seven respects without resorting to a cumbrous, costly, and possibly troublesome water-cooling system.

Why, may the novice not unnaturally enquire, have these seven valuable items been discarded from the temperament of the modern engine? Well, these ancient engines weighed considerably more than the 45 lbs. or 55 lbs. of their up-to-date compeers. The total machine scaled a couple of hundredweights, as against the 160 lbs. of the modern 3½ h.p. type. An engine of the size I am speaking about seldom ran up to more than 1,800 r.p.m. when fitted with a standard gear, and to a motor bicycle; whereas some modern engines touch 3,000 r.p.m. as an ordinary thing. The modern compression is far higher, and a greater b.h.p. is extracted from the same dimensions. If modern demands allowed a designer to fit a very much heavier engine, developing only 2¾ h.p. from a bore and stroke of 84 mm. or so, none of the seven charges detailed could be brought against the engines of to-day.

Popular Preference.

There is no doubt which of these engines is the more desirable. If I put a new make of motor bicycle on the market, complying with modern practice in every detail except the engine, and fitted with one of these old De Dion or M.M.C. engines, I should not sell half a dozen in a year. The public demand with no uncertain voice a light and highly efficient machine, and to obtain this they are willing to put up with other things as described.

The Remedy.

Water-cooling is suggested as the best remedy for perfecting existing patterns. It is necessarily costly; it is simply bound to add a few sovereigns to the selling price. The only standard motor bicycle with water-cooled engine now sold costs £55, in spite of the simplicity of its engine, as against the £48 to £50 of air-cooled machines of equal power. Water-cooling is bound to introduce a new source of trouble. Well made, it will be reliable for a certain period, probably a long period; but in the end the radiators and piping of the most costly car give trouble, and very often accidents intervene and give trouble before natural derangement has set in. On the other hand, it is easy to see that troubles Nos. 1 to 7 will in time disappear without any such harsh measures as a complete remodelling of design. In fact, they are already disappearing, and have been very greatly modified within the last two or three years. A better understanding of metallurgy will give us valves which do not break, and rings which will wear longer. A very slight modification of carburetter design will prevent dust entering the cylinder *viâ* the carburetter. The hinged petrol drain tap has already reduced the starting trouble to inconsiderable dimensions. Lower compression is also minimising knocking and overheating. Better design of piston rings, coupled with refinements of lubrication, are reducing wear of the cylinder bore. In conclusion, I look confidently forward to the near future when I shall buy an air-cooled motor bicycle of light weight and extreme efficiency, which will not be marred in use by any of the seven troubles included in my list.

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, E.C., and should be accompanied by the writer's full name and address.

A Cure for Puncture Troubles.

[4518.]—One still hears a lot about puncture troubles on tours and in competitions, but a preparation called Miraculum does not seem very well known. I put a tube of this in each tyre of my motor cycle over a year ago, and the only trouble I have had is to pull out the nail, thorn, or glass, pump up, and ride off—time three minutes.

I have motor cycled a good deal on these Spanish roads without taking a spare tube or outfit, picking up many nails, glass, etc., in the back tyre, but the front still has Coventry air in it. I have no interest in the makers of this preparation save that of a satisfied user.

Gibraltar. L. M. BARNES.

A Suggested Aid to Valve Removing.

[4519.]—I often wonder whether the commercial valve remover has a ready sale, as it always struck me as being such a clumsy tool to carry with one (and it is useless possessing one if it is not always in the toolbag). I thought perhaps an equally efficient and more convenient substitute would be of interest. This simply consists of a wooden plug or disc which will fit loosely on the valve head, and of such a height that when the valve cap is screwed down a few threads the plug is pressed down on to the valve. With this in position the raising of the spring by leverage with a screwdriver against a radiator fin is extremely easy, and the cotter can then be removed with pliers, or even the fingers. It will answer on almost any machine with side by side m.o.v. PLUG.

Ease of Starting.

[4520.]—May I say how cordially I agree with the writer of the paragraph on the above subject in a recent issue. I believe there is nothing that will promote the use of the motor cycle so much as a fitment that would make it as easy to mount and start as a pedal bicycle. Take my own case, and I have no doubt there are thousands of similar ones, I should certainly have got a motor cycle several years since but for the trouble of starting. When I saw younger men having to run by the side of their machines to get up steam and then to mount while the machine was in motion, I knew it was no use my investing in a mount which required a feat of gymnastics every time before it could be ridden, for I am neither young nor active. I am still waiting for a motor cycle to be marketed that will be as easy to mount and ride away as a pedal bicycle.

H. ALLEN.

Increase of Speed on Slightly Raising Exhaust Valve.

[4521.]—This question has struck me as being easily explained. The exhaust valve of all motor cycle engines has a strong spring which closes the valve sharply like striking a blow with a hammer. When striking a blow with a hammer on a piece of solid iron the hammer will rebound. I think this is what happens to our exhaust valve. Instead of it closing as we think it does it drops on the seat and bounces up again, and so allows a portion of the explosion to get past. By partially lifting the valve as we think we simply "take the weight" of the valve and let it gently down on the seat, so stopping the rebound. This is the reason, I think, of the increase of speed obtained when the engine is running fast. No doubt we should obtain the same result by fitting another spring to act in the opposite direction and so break the force of the blow and form a cushion.

W. G. DARGIE.

Improvements in Detail.

[4522.]—Mr. Fred Stuart evidently misunderstood some remarks of mine in a recent letter to *The Motor Cycle*, the tail end of which was, I confess, rather carelessly expressed. My point was not that the valves on my Triumph need specially frequent grinding in (which is certainly not the case), but that, whenever it becomes necessary from any cause (*e.g.*, when scraping deposit off cylinder) to remove a valve, it is more convenient to have a proper valve extractor for the purpose than to run the risk of breaking one of the radiating fins of the cylinder by using a screwdriver or spanner as a lever, which is, I believe, the clumsy resource of a good many riders.

If only this most courteous but busiest of all firms would give me a bayonet-joint fitting for the tops of the gas and air pistons, I would ask nothing more. In conclusion, might I suggest to Mr. Stuart that one of his piston rings is either too tight a fit or else is broken and has jammed, and that if he will unship the cylinder he will probably discover the reason for the suspiciously good compression of his engine after 3,000 miles work. My weight is seventeen stones. AUSTIN LESTER.

Coupling Attachments.

[4523.]—Having noticed in *The Motor Cycle*, which I have taken regularly for three years, that several readers have asked for experiences with a pedal bicycle coupled to a motor bicycle, I beg to say that my wife and I have had some very delightful rides so coupled. My coupler is the Unito. The steering is like an ordinary motor bicycle—after the first mile the passenger attachment is not noticed. Our first ride was thirty miles; no trouble whatever. With long spindles in the front and back wheels of the pedal cycle to enable lock nuts to be fitted the coupling is perfectly safe; of course, we do not take corners at twenty miles an hour. I have taken my wife from East Grinstead to Pevensey Bay, starting on a rise from home and then through Ashdown Forest to Hailsham, plenty of corners from there to the Bay, and she has not had to pedal a stroke on her machine. My motor is a 3½ h.p. Kerry, 1904 pattern. The vibration to passenger is not great. I have not been a passenger, but my wife and a male friend both say they do not notice any to speak of, unless the road is very rough; even then spring forks and a spring seat-pillar would no doubt absorb a good deal of it. The makers' instructions must be carefully followed when fitting, and the measurements noted; after that the attachment may be uncoupled and the fittings carried on either machine when used for solo riding. W. J. AVERY.

Mr. and Mrs. Avery, who use a Unito coupling attachment, their experiences with which are related in the accompanying letter.

Road Dangers at Night.

[4524.]—I have read with interest the letters in your valuable paper on road dangers at night, and should like to tell you what befell me about three weeks ago.

I was coming home from one of my country journeys. It was pitch dark and raining fast, when suddenly I struck something, and when I had picked myself up I discerned that I was in the midst of a dozen or so cows.

I sprained my wrist badly; the lamp and handle-bars were smashed, also the footrests. The repairs cost me 34s., and I had a narrow escape of being very seriously injured. Of course, the drover had no light at all. It is a disgrace that no law compels drovers to carry a coloured light.

F. JOLLIFFE.

A Puzzling Case.

[4525.]—With reference to Mr. Lucas's article, "A Puzzling Case," in the issue of January 10th, I have had exactly the same experience with my 1909 3½ h.p. Humber. Every time I opened the throttle wide the engine would come to an absolute stop, but would start again quite easily just afterwards. This occurred on about twenty occasions, and I managed to find out the cause just before I read Mr. Lucas's article. A new Oleo plug entirely cured the trouble, and I have not had it occur since. I have examined the old (Oleo) plug, which has been over 3,000 miles, and find the points have been fused. Used in this condition the plug retains the heat, and after running the engine fast for some time the points get very hot. On opening the throttle wide the increased heat from stronger explosions causes the points to get white hot, thus exploding the mixture too early. Using a plug in this condition causes the engine to overheat considerably, as the spark does not occur so quickly with an old fused plug as with a new one, consequently more gas has to be given to do the work.

Mr. Lucas mentions that both plugs had been over 1,000 miles, but of course some will last much longer than others. Thanking Mr. Lucas for his straightforward article,

A. C. ROBBINS.

The Transmission Question.

[4526.]—"Civil Engineer" rather oversteps the mark in saying that motor cyclists resemble a flock of sheep. A more shrewd class of men does not exist. He lauds the Whittle belt and criticises the rubber belts. My experience has been entirely different with regard to rubber belts. My last belt—a Shamrock-Gloria—ran seven months (all weathers) without being shortened, and I cannot remember removing the belt from the pulleys during that period. I was not troubled with slipping or fasteners breaking, and I am using the same Stanley hook fastener in a new belt.

My machine is a 3¼ h.p. and fast. Bad weather does not stop me, nor greasy roads, not even in darkness or fog. "Civil Engineer" must be wrong in saying the belt does not wear the pulleys. I find a rubber belt wears my pulleys considerably. He also forgets that if he gets more mileage with a Whittle he loses it in the pulley bearing by extra wear of that part. Perhaps he has not noticed how the old chain-driven machines threw the oil from the sprocket side bearing all over the rider and machine, due to nothing but the rigid drive and no slipping medium, thus wearing the bearing.

Surely he does not compare a Whittle belt with rubber and canvas for flexibility. If the Whittle fits the pulleys perfectly it can only be compared with a chain. With a rubber belt apply the brake to the rear wheel with the engine running on the stand, and watch the belt give without slipping, which must lengthen the life of the bearings a great deal, besides putting no strain on the engine.

Although I have had such satisfactory results with belts, my next mount will be a shaft-driven one, as the belt throws mud all over the machine—my only objection to it.

PONY.

Beaded-edge v. Wired-on Tyres.

[4527.]—I would like to add my experiences to the present little controversy in your columns, "Beaded-edge or Wired-on Tyres." Up to 1907 I always had a standard pattern motor cycle with beaded-edge tyres. In that year the T.T. model was born, and I ran a 1907 standard with beaded-edge tyres alongside, so to speak, a T.T. with wired-on. I had ridden some 6,000 miles when the T.T. came on the scene, and before long it required a very great effort on my part to leave the T.T. in the shed and go out on the standard. I tried all sorts of dodges, changing over wheels, engines, etc., at various times, and came to the conclusion that the wired-on tyre was faster, and enabled the machine to pick up more quickly, and it gave an increased flexibility (incidentally, I lost my taste for the standard frame with pedals). As far as reliability goes, I think I cannot do better than state what happened to my tyres (2in. × 26in. wired-on Dunlops) in each of the last Six Days' Trials.

In 1907 I had seven punctures (due to seven nails), but although these tyres are reputed to be hard to detach, they came off and went back rapidly enough to prevent any loss of marks.

In 1908 I had one thin wire nail through the back cover.

In 1909 I again had one puncture (a nail). My tyres in 1908-9 were in splendid condition at the finish; in fact, in 1908 I called the judges' notice to the state of the treads, for there was not a single scratch visible, and that after crossing the Grampians.

In 1907 I wore out the same number of covers on each machine in approximately the same mileage, roughly, one cover every 2,000 miles on the back and every 3,000 on the front. Once a tyre begins to go I scrap it.

F. C. MUSTARD.

Experiences with a 3½ h.p. and Sidecar.

[4528.]—As the performances of motor cycles with sidecars seem to be evoking considerable interest, the following may interest those of your readers who contemplate sidecaring during this year.

I bought my Phelon and Moore and sidecar in August last, and since then have done about 2,000 miles. I find that the combination will not average more than seventeen and a half miles per hour over give and take roads, but it will climb practically anything on the low gear; I have only had to shed passenger once. If the gear is kept clean, *i.e.*, free from excess of grease, the machine without sidecar will take absolutely anything on top gear solo, and it is a real treat in traffic or on grease, once the rider has become thoroughly at home with the gear manipulation in conjunction with the throttle and half compression levers.

Mr. W. Welford and his 3½ h.p. two-speed P and M. and sidecar. (See accompanying letter.)

The accompanying photograph was taken at the Blackpool Aviation Meeting last October, the run back being made *viâ* Preston, Clitheroe, Skipton, and Boston Spa; a long detour involving something like 160 miles was done in pouring rain and without the slightest trouble.

In conclusion, if one is content to travel at a comfortable jog-trot pace of sixteen to seventeen miles per hour, one need not have any qualms with regard to sidecaring with a P. and M.

W. WELFORD.

Water-cooling on Motor Bicycle Engines.

[4529.]—I was very glad, when opening my copy of *The Motor Cycle* of January 3rd, to read "Ailette's" article on water-cooling of motor bicycle engines, and to find his opinion backed up on January 10th by "Rotator." Whilst both these writers are agreed as to the many advantages which water-cooling would have over air-cooling, both appear to think (especially the latter) that there are a good many obstacles still in the way.

Among some of the drawbacks mentioned are unsightly radiators and water pipe connections, increased weight, and reduced petrol and oil capacity. I am glad to be able to be in a position to tell your contributors and all others interested in the subject that these drawbacks do not exist in the machine I am using.

I was fortunate enough to get hold of one of the few Green's water-cooled engines referred to by "Ailette" about three years ago, and any doubts I may have had as to its many merits were quickly shunted directly I had the opportunity of comparing it with my previous mounts.

My machine has no unsightly pipes and connections, neither is the weight increased beyond the very small quantity of water required (about 3½ lbs. only), and the tank capacity is not reduced. My valves I never look at for many months together, the cylinder and piston remain so free from carbonisation I don't know what premature firing means, and engine starts from cold at any time without having to tinker with a paraffin squirt. The greatly increased power over any air-cooled engine of the same size and its flexibility were a revelation to me, as it is to all my friends.

I may here mention one little incident which occurred last autumn: Whilst out with a friend each with a sidecar and carrying full average weight passengers, my friend's motor failed him, and I was obliged to take him in tow—sidecar, passenger, and all—and except for the stiffest hills neither of them had to dismount for the twenty miles we had to do to get home. This happened when we were in the neighbourhood of Wadhurst, not far from Tunbridge Wells, which will be appreciated by all those familiar with this district.

Since I have had the machine I have driven many thousands of miles over all kinds of roads and in all weathers, both alone and with sidecar and passenger, and have never required to use the pedals—in fact, I have not got any—and, generally speaking, I have been free from many little troubles I used to have with my air-cooled machines.

Lastly, I must not forget to mention economy of running. The saving in this respect is considerable, especially as regards lubricating oil. The consumption of this is ridiculously small.

In conclusion, I can only hope that these few remarks by one who has had the opportunity of putting a new idea to a practical test for a considerable period may prove of some little interest to your readers.

C. CATT.

Of course, the motor cycle is playing a part in the election. The photograph shows Mr. W. Gibbons using his two-stroke Scott motor bicycle and sidecar to convey a voter to the polling station. It is said that the above combination had a great deal to do with Mr. W. Hayes Fisher's success at Fulham!

Lightweights v. Heavyweights.

[4530.]—I notice in Mr. Robinson's letter [4497] his explanation of the weights of the Douglas machines in the M.C.C. petrol consumption trial last September. The fact that it was necessary to weigh up the machines in order to benefit by the 30% extra allowance of petrol (which was really intended for heavyweight machines) shows in my opinion that the makers had not much faith in their standard machine winning on petrol consumption.

With all due respect, I would like to remind Mr. Robinson and your readers that all machines, lightweights included, were hopelessly beaten in this trial by a heavyweight machine, namely, Mr. R. C. Davis's 5½ h.p. Griffon, which did many more miles per gallon than any other motor cycle. The fact that I was an assistant at the scales does not prevent my referring to the weights published in your paper. If Mr. Robinson will read my letter [4455] again he will see it is not I who assume the weight of the Douglas to be 150 lbs. I only gave the published weights. When Mr. Robinson says that I rushed into print he is entirely wrong, as it was only after some weeks' consideration of this matter that I decided to refer to it in a letter. Personally, I do not think the general public cares a brass button whether a lightweight will do 133 or 233 miles to the gallon so long as it will wear well and is reasonably comfortable for the purposes for which it is intended.

May I repeat that I have nothing but admiration for the Douglas machine and its performances, but that I fail to see how a machine weighing 120 lbs. in riding trim can be termed a lightweight. Rather would it be better at once to acknowledge it as a medium weight machine.

HAROLD KARSLAKE.

[4531.]—I canot let Mr. B. G. Durkin's letter in the issue of December 27th go unanswered, as I am neither "over forty and married," nor are my "nerves in such a state that I avoid all towns." On the contrary, I am younger and in quite the same condition as he describes himself to be, and yet I prefer a lightweight for all the year riding to a heavyweight. My experience is considerably longer than his, and on machines from 1¾ h.p. to 6 h.p. My present machine—a 2¼ h.p. Moto-Rêve—is the easiest machine imaginable in traffic, as it will run so beautifully slowly. I grant him that the maximum available speed is lower, but then I can always average well over the legal limit for hours at a stretch. Because he finds more pleasure in a high-powered heavyweight it is no reason for him to run down all others. I should like Mr. Durkin to drive his machine every day, say, from Clapham to Highgate for a week, and then do the same with a lightweight, and say which he prefers.

G. L. ANDREWS.

EXPERIENCES WANTED.

"H. B. R." (Monkstown) would like readers' experiences with the A.S.L. motor bicycle.

"Enquirer" (Hampstead) would like readers' experiences with the A.C. sociable tricar, particularly with regard to reliability, silence, hill climbing, cost, and comfort.

"Second-year" (Wakefield) would like readers' experiences of a 1909 Humber two-speed model.

THE MOTOR CYCLE IN THE UNITED STATES.

By EARLE L. OVINGTON.

I WAS very much surprised, as well as somewhat grieved, to read in the issue of January 3rd the article by "Transatlantic," entitled "The Motor Cycle in the United States." As one who is thoroughly acquainted with motor cycle conditions—not only in the States, but in Great Britain as well—I am, perhaps, qualified to criticise this article.

If the friend mentioned by the author of the article had not actually visited the States I should have concluded that he had been misinformed with regard to the actual conditions of affairs. However, I can only assume that in examining American motor cycles he was unfortunate enough to come in contact only with old models: and even if this were the case some of the statements are not correct.

Taking the article as a whole it is entirely misleading, and contains many statements that are absolutely false.

Different Countries have Different Ideas.

To be specific, it is to be expected that motor cyclists on this side of the water have certain ideas which, it is not surprising to learn, differ materially from those held by enthusiasts of the motor cycle in the States. If we prefer a certain type of tank, a certain frame outline, and, perhaps, rather brilliant enamels, it seems to me we have a perfect right to use these, and it is a little unfair for motor cycle enthusiasts outside the States to criticise our tastes, much less to say that they do not follow good engineering practice. There are certain fundamental principles, however, involved in motor cycle design, and in whatever country the motor cycle is made these should be followed. As far as mechanical construction and efficiency are concerned, we motor cyclists of the United States welcome the criticism of our English cousins; but as far as the appearance of the machine is concerned, that is something which we must decide for ourselves, and which is governed by our own tastes.

"Transatlantic's" friend states: "Very few makers have yet adopted the magneto as standard, though many are ready to fit it as an extra." That was the state of affairs about two years ago. Last year practically every prominent maker marketed a magneto machine as standard, and this year I do not know of a single exception where this is not the case.

"Some of the few stands I saw were worse than useless." If this is the case, all I can say is that the stand, which is practically a regular equipment on all the prominent makes, was a direct copy of the stand used on the Vindec, which is the identical type used on most of the English machines. We have found it very efficient indeed; in fact, as far as I have been able to observe, it leaves nothing to be desired.

Frame Design.

As to the advantage of using the loop type of frame with the engine bolted to clips, or what "Transatlantic's" friend calls a straight tube frame, where the engine is clamped to the frame and the crank case serves as a part of the frame structure itself; here again opinions differ. Looking at it from a strictly engineering standpoint, I believe that the loop type of frame is, if anything, stronger than the straight tube type, and I believe it is an error when he states that the latter type of frame is lighter than the former. In one case we have a firm mechanically-correct frame, and in the other we have tube members of the frame divided in order to introduce the crank case of the engine. Again this is a matter of appearance, for I think there is little to choose between the two types from an engineering standpoint.

There is one very good criticism of American machines which says that the exhaust piping is often long, thin, and full of bends. Americans attach a good deal of importance to appearances, and the type of tubing described is often necessary in order to place the silencer behind the bottom bracket and just clear of the rear wheel. The very fact that American engines give the service they do with such an exhaust pipe, and that we have so little trouble with our exhaust valves, seems to me to speak volumes in favour of American engine design.

Reliability Contests.

The paragraph which reads, "Of course the majority of American makers have never had to cater for reliability in the same sense that our makers regard it, for most of their customers only use their machines for short excursions to suburban resorts, the country roads being so unspeakably vile," is, I am afraid, the opinion of one who does not read our motor cycle periodicals, nor does he follow very closely reliability runs in the United States. British reliability contests usually extend over a greater time than ours, but as far as strenuous riding is concerned I do not think British riders really know what it is. On our endurance runs we often strike sand six or eight inches deep for many miles at a time, hills several miles in length with a very rough road surface, and it is not at all unusual for a motor cyclist to be thrown violently from his machine by being forced to ride over a rock larger than his head.

At the conclusion of the article it is acknowledged that a large percentage of our riders get through these endurance trials with credit; that is not because such contests are not made difficult enough, but because many of our riders are expert in driving a motor cycle over very rough roads with locomotive-like regularity.

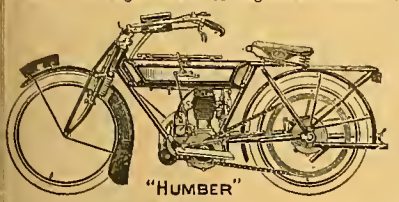
The Transmission Question.

The statement that the chain drive is an easy winner over the belt, that it is simply due to the shoddy nature of most Yankee belts, and that it is impossible to obtain a decent belt of American manufacture, is quite erroneous. It may be of interest to "Transatlantic" and readers of *The Motor Cycle* when I state that from my positive knowledge there is not a single prominent American manufacturer of belt-driven machines who does not use a foreign belt, and in every case—with one exception—the belt is the Shamrock-Gloria canvas and rubber belt, used so universally in England. The one maker who is the exception uses your own leather Watawata belt.

Taken as a whole, therefore, the article by "Transatlantic" does a great injustice to the American motor cycle industry; and from the statements made "Transatlantic" has shown that he is in one of two positions—either he is not as well informed as he would lead us to believe by his article, or else he is wilfully trying to mislead the motor cyclists of England.

QUALITY.

'e have the largest stock of High-class Machines.



"HUMBER"

ist received from makers, a few

1909½ HUMBERS

nd new. These you can hardly tell from 1910 models, g fitted with improved pattern silencers, spring forks. er pulleys, Roc licensed two-speed gear, H. B. control stered tank, high tension magnetos, Dunlop tyres, oil ip operated by foot, stand and carrier, toolbag with ools fitted to handle-bar. Fully guaranteed.

£42 10s., or exchange, or credit.
SPECIAL DISCOUNT FOR CASH.

09½ SINGLE SPEED HUMBERS.

rand new, fitted with latest pattern silencers, spring s, magnetos, pedalling gear, stand, carrier, toolbag, s, number plates,

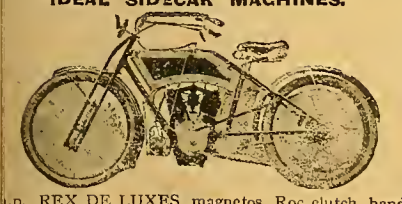
£37 15s., exchange or credit.

ash offers wanted. Why buy second-hand machines n brand new, up-to-date, fully guaranteed machines be had at these prices. Remember number is limited.

NEW 1909 ARNOS.

'e have a few Brand New 3½ h.p. Models, fitted with netos, h.-b. control, complete with tools, etc. ist price, £45. Our price, **£32 10s.** Or exchange. Cash offers wanted.

IDEAL SIDECAR MACHINES.



.p. REX DE LUXES, magnetos, Roc clutch, handle starting, spring forks, spring seat. plete with sidecar, **£27 15s.** Or exchange. Cash offers wanted.

edit or Exchange. Send for List.

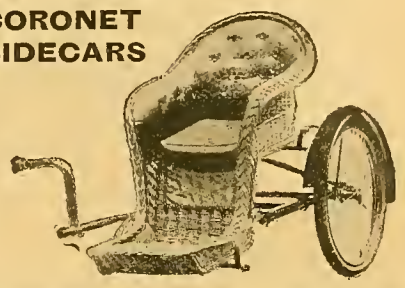
SPECIALITIES.

£4 17s. 6d.
CORONET SIDECARS



Before buying a Sidecar, send for illustrated circular explaining the advantages of "CORONET" Sidecars over other makes. Delivery from stock to suit Minervas, Rexes, N.S.U.'s, Triumphs, and any other make. Attached in three minutes.

Price £4 17s. 6d. Discount to trade.

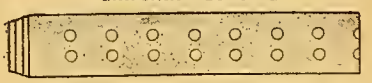
CORONET ADJUSTABLE PULLEY.

12/6

The best variable speed pulley on the market. Loose flange securely held in any position by a simple yet ingenious contrivance. Gear can be altered without the aid of spanners, lock ring easily operated by hand. Buy a "Coronet" pulley and gear your machine suitable for hill-climbing.

Standard makes, such as Rexes, Triumphs, Minervas, supplied without the necessity of sending old pulley for pattern. **Discount to trade.**

"GRIPSKIN" BELTING.



Made from selected parts of hides, correct angle, perfect drive; the best leather belt on the market. Longer life than rubber.

⅝in., **10d.**; ¾in., **11d.**; ⅞in., **1/1**; 1in., **1/2**.

TRICARS FOR SALE.

6 h.p. Twin Air-cooled Tricar, open frame, Chater-Lea, inclined wheel steering (like racing car), three speeds, free engine, bucket seats, racy and very smart; absolutely must sell; take £16 (worth £25).—17, Kenmure Rd., Mare St., Hackney.

10 h.p. Lagonda Tricar, three times successful London-Edinburgh, in splendid condition, engine rebushed 10 months ago, also new gears and chains, tyres perfect, many spares; cost £130, price £32, worth double; to be seen at Finchley Rd. Garage, adjoining L.N.W. Station.—Write, E. W. Brewerton, 84, Wimpole St., W.

5 h.p. Twin-cyl. Light Tricar (Rex Triette), Bosch magneto, two-speed gear, in rear hub, Roc clutch, handle starting, cane forecarriage, footboards, special 1¼in. Watawata belt, adjustable pulley, Brooks saddle seat on Rex spring seat-pillar, complete with lamp, horn, and spares, registered; can be seen in Midlands; price £40.—No. 3,883, *The Motor Cycle* Offices, Coventry.

SIDECARS AND FORECARS.

NYE'S!—Chater-Lea sidecars are good! Try one. —69, Leather Lane, Holborn.

LIGHT Forecar, 26 wheels, perfect condition, wicker basket; 55s.—Kenworthy, Walpole, Wisbech.

SIDECARS, £4 17s.; baskets, springs, fittings; trade supplied.—Middleton and Co., Watson St., Newington Green, London, N.

CHATER-LEA Upholstered Sidecar, good condition; £4, or exchange engine, 2¾h.p.; any evening.—Hole, Lavender Rd., Wallington.

MONTGOMERY Sidecar, flexible joint, nearly new, wicker body, not upholstered; offers.—Stimpson, Pickersleigh Rd., Malvern.

MONTGOMERY Sidecar, almost new, 26 by 2½ tyre, £5; also nearly new speedometer, Cowey, £3 10s. —Duxbury, 40, Blackburn Rd., Darwen.

OUR Sidecars Talk. — New, with Michelin tyre (not new clearance), £5 5s.; perfectly satisfactory; one second-hand, £3.—128, High Rd., Tottenham. 1982, Tottenham.

LATEST 12 guinea sidecar, brand new, and built throughout with genuine Chater-Lea fittings; £6 6s.; wanted, Sunbeam cycle.—H. Bert, 9, Gaskell St., Clapham, London, S.W.

BRAND New 1909 Montgomery, flexible, wicker chair, upholstered green, non-skid, apron, 26in. wheel, never used; cost £10 10s.; lowest cash £6 15s.—Wallis, grocer, Hills Rd., Cambridge.

J. DAVIS, Automobile Engineer, Barnsbury Grove, N., begs to inform readers that he is the inventor and sole builder of the protected double-seated sidecar, illustrated recently in *The Motor Cycle*. This sidecar, with tiller steering, is the last word in comfortable motor cycling. Particulars and prices on application.

DID You Visit the recent Stanley Show?—If you did, you have seen with admiration and heard the chorus of unanimous approval of our new patent Homegaraged sidecar, which, together with the cycle, stand, and can be wheeled about without detaching in the space of 23-26in. Your own old sidecar converted into a Homegaraged one for £1 17s. 6d. Send us yours; no crate required.—Bramson and Co., 5, Farleigh Rd., Stoke Newington, N.

QUADCARS.

FOR Sale, Phœnix quad, very good condition; nearest offer £30 has it.—Webb, 37, Gt. St. Helens, Bishopsgate, E.C.

8 h.p. Phœnix Quadcar, twin water-cooled Fafnir, two speeds and reverse, splendid condition; £37 10s.—128, High Rd., Tottenham.

ARIEL Quad, two speeds, Amac carburetter, h.b. control, car tyres, splendid condition, reliable; £20.—77, Upper Clapton Rd., N.E.

PHŒNIX Quad, 2 cyls., seat two, magneto ignition, in new condition, wheel steering, painted French grey, detachable front seat, with bonnet to replace; client leaving the country; cost £127, to clear, £45.—Apply, Turvey and Co., Garage, Sunderland.

CARS FOR SALE.

9-11h.p. Clement Car, 4-seater, £70; another at £48; Swift single-cyl. 2-seater, £45.—Carr's Motors, Bury.

7-9h.p. Star, three speeds and reverse, 2 or 4-seater, 810 by 90 wheels, perfect; trial; £47 10s.—Below.

4½h.p. De Dion Phaeton, two speeds, perfect condition; £18 10s., or exchange.—128, High Rd., Tottenham.

8-10h.p. Deschamps, 2-seater, racing type body, raked steering; £35, or exchange.—16, Triangle, Bishops Rd., Fulham.

DARRACQ, 9h.p., single-cyl., three speeds and reverse, 4-seater, solid tyres new; £35.—T. Church, Worsboro' Dale, Barnsley.

9 h.p. Darracq, detachable tonneau, hood, three speeds, reverse, cardan; £45; part exchange.—20, Potternewton Lane, Leeds.

SMALL 2-seater, 5h.p., two speeds, engine under bonnet, splendid throughout, tyres included; £20.—30, London Rd., Blackburn.

O.T.A.V., smart 2-seater, complete with hood and lamps; £35; photo; good motor cycle part payment; bargain.—28, Woodbridge Rd., Ipswich.

WHEN

"ALL'S WELL"

with the engine all's well with the motor bike. If you would have "all well" with the engine give

CHEMICO
MOTOR BIKE OIL

a fair practical test, you'll want no other.

TOM PECK who used it on his End-to-end ride, wrote of it—

"I found it everything one could wish. I had no trouble from over-heating as my engine was running as well and as sweetly when I reached John-o'-Groat's as when I left Land's End."

Can you say as much for the oil you are now using? Ask for Grade A, specially prepared for general winter use.

THE MOTOR CYCLE SUPPLEMENT

The Association of Motor Cycle Manufacturers and Traders.

A MEETING of representatives of the motor cycle trade, held by the Association of Motor Cycle Manufacturers and Traders, took place at the Holborn Restaurant on Wednesday afternoon. Mr. J. R. Nisbet was in the chair. In opening the meeting, the Chairman recounted the doings of the Association since its formation at the last Stanley Show, and mentioned that the Society of Motor Manufacturers and Traders and the Cycle and Motor Trades' Association had been invited to send delegates to point out the advantages offered by their bodies. It had been suggested that this Association should join forces with the C. and M.T.A. The meeting had not been called solely to deal with the show question, but other business was to consider whether a separate association should be definitely formed or the present Association should join forces with the C. and M.T.A. In the event of an alliance there would be formed a special motor cycle section, which would enjoy the same advantages as if a separate body were formed, and, in addition, it would have a separate title, offices, and secretary.

Mr. Bednell (secretary C. and M.T.A.) stated that about thirty manufacturers of cycles and motor cycles, including all the principal ones, and thirty makers of proprietary articles formed the membership. As regards a title, it had been already suggested that in the event of an agreement between the two bodies the name of the Association would be the Cycle and Motor Cycle Trades' Association. The idea that a combined show at Olympia would be held had every prospect of being revived.

Mr. Mann (the Service Co.) asked if agents would be allowed to join, to which Mr. Bednell replied that only manufacturers or manufacturers' representatives would be admitted at present.

Mr. Harry Smith (the Rover Co.) said if the manufacturers were unanimous it would be quite possible to hold a good show of motor cycles and pedal cycles at Olympia, which could be rented from the Society.

The proposal that the Association of Motor Cycle Manufacturers and Traders should join forces with the Cycle and Motor Trades' Association was then put to the meeting and carried *nem. con.* The meeting, which was well attended, concluded with the usual vote of thanks to the chairman.

British Motor Cycle Racing Club Fixtures.

EIGHT meetings have been arranged at Brooklands by the go-ahead B.M.C.R.C. for 1910 as follows: Wednesday, March 16th; Wednesday, April 13th; Wednesday, May 4th; Wednesday, June 22nd; Wednesday, July 20th; Wednesday, August 17th; Wednesday, September 21st; and Wednesday, October 19th.

The programmes have not, of course, yet been settled in detail, but riders of all degrees of experience will be catered for by the inclusion of the following:

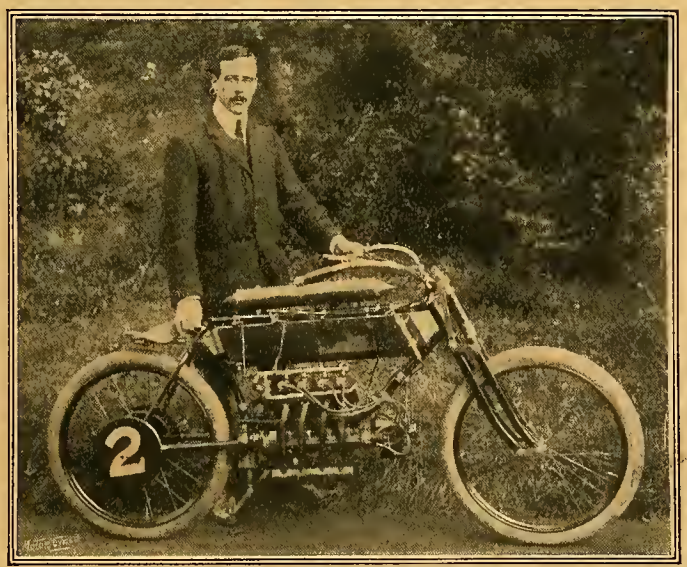
Three one-hour T.T. races before the Tourist Trophy Race is run in the Isle of Man.

A one and a two-hour race for all classes.

A five-lap racing speed judging contest.

The time trials for both miles and kilometres per hour rates, and with both flying and standing starts.

A five-mile time trial.



Mr. T. W. Loughborough, hon. sec. *pro tem.* of the B.M.C.R.C. Last year he was the successful exponent of a four-cylinder F.N. on Brooklands.

Team races.

Handicap races, based on previous performances made the same day.

The annual general meeting of the club will be held at 7.30 p.m. on Thursday, the 27th inst., at the offices of the Brooklands Automobile Racing Club, Carlton House, Regent Street, London, W.

Mr. T. W. Loughborough, Ashleigh House, Erith, Kent, has been appointed hon. secretary *pro tem.* of the B.M.C.R.C., in the absence of Mr. A. G. Reynolds, who has not yet quite recovered from his serious illness. Mr. Loughborough, it will be remembered, has been an exceedingly keen member of the B.M.C.R.C.

Lamp Lighting Times.

The times to light lamps this week are:

Mon., Jan. 24	... ...	5.31 p.m.
Wed., Jan. 26	... ...	5.35 p.m.
Fri., Jan. 28	... ...	5.39 p.m.
Mon., Jan. 31	... ...	5.44 p.m.

Racehorse v. Motor Cycle.

A novel race is on the *tapis*. Mr. Lionel E. Skertchly is to ride his 1909 T.T. Triumph against a 13 stone gentleman mounted on a racehorse. The match to be for £100 a side. Mr. Skertchly invites our readers' comments on the conditions. See Questions and Replies pages.

T.T. Race Entries.

Entries for the Tourist Trophy Race in the Isle of Man on May 26th are as follows: H. A. Collier (1 machine), W. H. Wells (2), Hendee Mfg. Co. (3), W. O. Bentley (1), Triumph Cycle Co. (3), C. B. Franklin (1), Noel E. Drury (1), H. Collier and Sons (2), Quadrant Motor Co. (1). Rex Motor Mfg. Co. (3), Scott Engineering Co. (1), W. H. Bashall (1), and J. T. Bashall (1).

The Projected Motor Cycle Show at Olympia.

The Society of Motor Manufacturers and Traders have decided not to hold a motor cycle section at the Aero Show in the spring, as the replies to the circular from motor cycle manufacturers gave but little support. It has also been resolved, subject to Olympia owners' permission, to sublet the hall to the Cycle and Motor Trades Association for extended time in November next, and to give the association the benefit of all arrangements possible for the holding of a cycle and motor cycle exhibition that month.

"The Motor Cycle" Buyers' Guide, 1910.

We have in course of preparation the 1910 "Buyers' Guide," which has been an annual feature of this journal since 1905. It will contain a complete list of British and foreign motor cycles at present on the market, together with a full specification of the different models and their list prices. The guide will be found invaluable to prospective buyers for reference purposes.

Manufacturers who have not received a form for filling in purposes should apply to us immediately.

Anything and Everything for a Motor Cycle.

The variety of articles offered in exchange for second-hand motor cycles is really amusing. Among the articles which were offered in the miscellaneous and exchange columns in our last two issues were a diamond pin and stud, joiner's tools, push cycles, motor cars, furniture, pianos and organs, diamond ring, oak bureau, phonographs, gramophone and records, typewriter, breech loading gun, flat of furniture, billiard table, and a piano player. The frequency of these advertisements shows a great keenness in the pastime and the large number of readers desiring to possess a motor bicycle

To Race at Brooklands.

Mr. A. Baker White, the well-known driver of high-powered racing cars, has returned to his first love—the motor cycle. Mr. Baker White last year possessed quite a stud of racing cars, and he was a regular competitor in Brooklands events. He is just as much at home driving a 60 h.p. Napier racer as a small touring car. Before he took to car driving he owned several single and twin-cylinder motor cycles, of varying horse-powers. He has just placed an order for a 3½ h.p. Trump-J.A.P. for racing at Brooklands, similar to the one illustrated in *The Motor Cycle* a fortnight ago.

American Records.

A list of "accepted motor cycle records" published in an American journal, and compiled by F. L. Valiant, shows that every amateur record has been created in America. The majority of the professional distance records are also credited to American riders. Cissac (2 records), H. Martin (1), and H. A. Collier (2), alone appearing on the list. All professional time records from one to twenty-four hours are "accepted" as belonging to British motor cyclists.

Next Saturday's Quarterly Trial.

The following entries have been received for the first quarterly trials of 1910:

Bicycle and Tricycle Class.

W. Cooper (3½ Bradbury).
E. Leighton (3½ Triumph).
Phelon and Moore (2¾ P. and M.).
W. W. Douglas (2¾ Douglas).
P. Phillips (2¾ Douglas).
G. Lee Evans (5 Indian).
W. O. Bentley (5 Indian).
J. S. Harwood (3½ P. and M.).
A. R. Abbott, jun. (8 Matchless).
H. G. Bell (2¼ F.N. tricycle).
F. A. Applebee (3½ Rex).
W. A. Lockwood (3½ P. and M.)
B. A. Hill (2¾ Douglas).
G. T. Gray (3½ N.S.U.).
Quadrant Motor Co. (3½ Quadrant).
A. T. Stanton (3½ Bradbury).
F. W. Applebee (5 Rex).
J. Gibson (5 Indian).
E. Kickham (2¾ Douglas).
Douglas Bros. (2¾ Douglas).
F. A. McNab (3½ Trump).
J. H. Slaughter (3½ Ariel).
Motosacoche, Ltd. (1⅞ Motosacoche).
S. A. M. Wittam (3½ Triumph).
Premier Cycle Co. (one 3½, and two 3¾ Premier).
Bayliss, Thomas, and Co. (two 3½ Excelsiors).
F. Thomas (6-7 G.O.K.).
A. L. Ommany (3½ Rex).

Passenger Class.

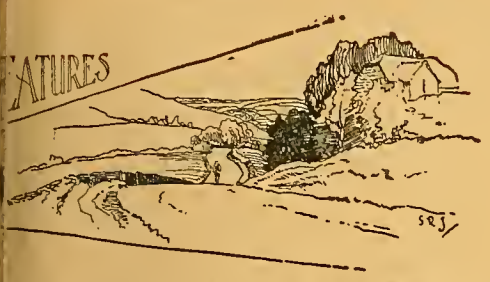
J. Tassel (8 Matchless and sidecar).
V.S. Cycle and Motor (7 V.S. and sidecar).
A. G. Fenn (5 A.C. tricar sociable).
Patent Gear and Motor Co. (3½ —— and sidecar).
J. Portwine (5 A.C. tricar sociable).
G. N. Higgs (5 A.C. tricar).

BENZOL AS A FUEL. THE V

Engine Features Criticised

Glenn H. Curtiss, the we aviator and motor cycle manu has designed a new pattern cylinder engine, the chief fea which is its off-set cylinder, o French term it, *desaxe* cranksh *Bicycling World* of America in ing the engine makes the followi ment: "Although this princ been applied to advantage in au engines, and also in certain cl steam engines, Curtiss is the fi neer to use it in a motor cycle But the writer is a long way b his facts. The credit belongs English designer in the person o A. Scott, the champion of the tw engine movement, and it is w note that all the two-stroke Scott have possessed the feature of a cylinder. The new Curtiss eng the way, has two overhead valve stems being inclined at an angle o

A new sport which is quite fas vagaries of oc



1,700 MILES ON A 7 h.p. TWIN.

each other, and open direct into nder. British motor cyclists are love with this type of engine, as, a valve break, there is nothing to it being jammed through the top piston. Curtiss has provided for earing connecting rod, and it will uctive to observe how long it is l. It is a significant fact that rominent British firms have tried bearing connecting rod of late ut in each case there was trouble, have returned to the plain bear- This is the more noteworthy, as motor cycle manufacturers the lead and popularised ball crankshafts.

Prices for Motor Cycles in South Australia.

ader mentions in a letter that a hand motor bicycle in Brisbane 50. New machines of first-class manufacture cost from £70 to

o onlookers! Unfortunately the moch practice.

A Tricar for Rural Postal Work.

A chain-driven tricar propelled by a J.A.P. engine has recently been pressed into service by the Sittingbourne Post Office authorities for local collection and delivery of mails. The tricar, which has had the front seat replaced with a large mail basket, runs between Sittingbourne and Frinsted, a distance of nine miles, linking up several villages and hamlets *en route*. There will be a couple of deliveries and collections daily. Time after time we have drawn attention to the utility of motor cycles for postal delivery work. Motor cycles are easily the cheapest and speediest vehicles for covering scattered areas.

THE AUTO CYCLE UNION SEVENTH ANNUAL DINNER.

The A.C.U. dinner was held at the Waldorf Hotel on Thursday evening last, H.S.H. Prince Francis of Teck, K.C.V.O., D.S.O., president, occupying the chair. This excellent dinner was well attended, but not many provincial members were present. After the royal toasts the Chairman rose to propose the Auto Cycle Union." In these days, he said, when there were so many unions, he was pleased to regard the A.C.U. as one of the most successful and go-ahead. It was full of activity and initiative, and carried out its duties in a manner deserving of respect. He then referred to the Six Days' Trial and the T.T. Race, the blue ribbon of motor cycling sport, and congratulated H. A. Collier on his success. There was in this race, he continued, an event which especially commended itself to him, and that was the pluck and tenacity of A. J. Sproston, who rode throughout the competition with a broken ankle, suffering great agony, and this greatly excited his admiration. His great regret was that he (the speaker) had not been present to congratulate him after the race. He then referred to the racing, legal, and other work done by the Union, and reminded those present to remember the good work done by the Auto Cycle Legion, and the way that work had been appreciated by Sir Edward Ward. The thanks of the members were due to the secretary and the whole staff. With the toast he coupled the name of Mr. Robert Todd.

Friendly Relations with Other Bodies.

Mr. Todd, to the amusement of the Chairman, said he was glad to be able to say, as was said in higher circles, that their relations with other bodies were friendly. He was pleased to note that the local centres were in working order. Members from the country came up and said they wanted the Union to be doing something; this, he said, was a good way of getting it done. These centres could do much good work. Provincial members, while they should recollect that the Londoners did not want entirely to rule the roast, must not be forgetful of the fact that London is not altogether an unimportant place, and sometimes people were glad to have an excuse for coming up. Touching the cattle on the highway question, he was glad to note something was being done, as people must get used to the new fast traffic, and not exclusively consider the traffic that was not fast, except fast asleep. However, the agriculturist had to be considered. While they could not compel everybody and everything to carry a light after dark, something would doubtless be done soon, but they must move slowly. He concluded by saying how pleased he was to see the Chairman there, and also Mr. J. W. Orde (secretary of the R.A.C.), the tried and trusted friend of the A.C.U.

Colonel H. C. L. Holden, R.A F.R.S., then proposed the toast of "The Affiliated Clubs," and stated that the Union should feel proud and honoured to be associated with the R.A.C. He concluded by referring to the success of the R.A.C. affiliation scheme, and coupled with the toast of the R.A.C. and the affiliated clubs the name of Mr. Orde.

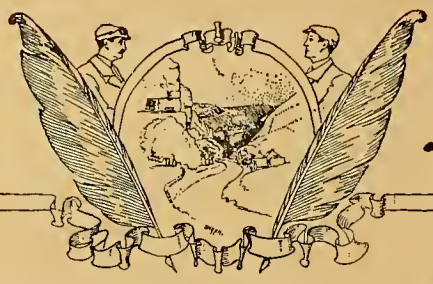
A Good Friend to the Union.

Mr. Orde, in reply, mentioned that though the Auto Cycle Union was one of the most important bodies affiliated to the Royal Automobile Club, it did not make the best of the advantages offered by the parent body. Mr. Todd was a good friend to the Union, but he hoped to be even a better, and the R.A.C. would be only too pleased to help the A.C.U. members. He then went on to refer to the splendid exhibition of pluck he had seen in the Isle of Man during the T.T. Race. In 1908 the membership of the R.A.C. and its associates was 10,000; now it is 17,000. He hoped the A.C.U. would progress with equal rapidity. Every member should get two or three people to join, and every club should increase its membership, and thus strive to swell the ranks.

Captain Sir R. K. Arbuthnot, Bart., R.N., in proposing "The Chairman," made a wholly irrelevant, altogether delightful, and really brilliant speech. Eulogising the Chairman briefly in his usual breezy manner, he talked of cut-outs, how foolish it was to seal them and then allow people to enlarge the holes; of the amateur question; of the lighting of cattle on the highway, mentioning that in Hong Kong every Chinaman had to carry a light and a number after dark (could not a leaf be taken out of their book?); and, lastly, of the Navy. On this subject the gallant Captain let himself go, and told the members not only the importance of a large and efficient Navy for the safety of our shores and those of our colonies, but the best way to get one, and, moreover, what would certainly happen if we did not get one.

After the Chairman had replied in a few well-chosen words, he distributed the prizes, and at the conclusion of a very excellent entertainment the proceedings came to an end.

CLUB NEWS



Norwich and District M.C.C.

A general meeting will be held at headquarters to-morrow (Tuesday) at 6.30 p.m. to discuss programme for 1909. All members are earnestly requested to attend.

Middlesbrough and District M.C.C.

On Wednesday evening, at the Corporation Hotel, Middlesbrough, at 7.45 p.m., Mr. A. Lauriston (the club's hon. solicitor) will read a lecture "The Law and its Relation to Motor Cyclists and Car Owners."

North-west London M.C.C.

At the recent annual general meeting Mr. G. Rowden was elected to the captaincy. Mr. T. G. Blundell resigning the position of vice-captain, Mr. H. V. Bate was elected in his place. Messrs. C. A. Stern and G. H. Hollis retain the positions of hon. secretary and hon. treasurer respectively.

Western District M.C.

At the annual general meeting the following amendments were made to the existing rules:

1. That an entrance fee of 2s. 6d. be now charged.
2. The headquarters of the club are now removed to the Green Man Hotel, Uxbridge Road, West Ealing.
3. The question of reaffiliation to the A.C.U. was left to the new committee, who are approaching the A.C.U. on a question which the majority of the members would like to have settled before deciding on affiliation.
4. Mr. T. A. Williams was elected a life member of the club in consideration of his past services.

The following are the officers and committee for the present year: President, Edward Smart; chairman, P. Snelling; vice-chairman, N. Hall; captain, H. E. Vowler; sub-captain, D. Steeves; auditor, W. F. Ritchie; committee, Messrs. Tweedie, Moss, Eagles, Butler, Dobson, Buckmaster, Thomas, Holloway, Caudwell, Armstrong, and L. Holloway; sports secretary, H. J. M. Hughes; hon. secretary and treasurer, I. J. G. Babbage.

A committee meeting is fixed for Friday, the 4th prox., at the new headquarters. The secretaries will be glad to hear from members who have suggestions for competitions and runs.

Bolton and District M.C.C.

The annual general meeting was held at beadquarters on the 19th inst., when it was decided to again affiliate to the Auto Cycle Union. The subscription was raised to 7s. 6d., which includes affiliation. The following are the officers and committee for the present year: President, A. R. Batten; chairman, S. Groom; vice-chairman, F. Taylor; joint secretaries, J. Foster, 34, All Saints' Street, Bolton, and J. Fishwick, 9, Georgina Street, Moses Gate; treasurer, J. Peters; captain, J. Fishwick; vice-captain, A. Horrocks; committee, Messrs. A. Richards, Nuttall, Yates, Woodall, Street, Orrell, Smith, and Green. Subscriptions are now due. Readers wishing to join should communicate with J. Foster, 34, All Saints' Street, Bolton.

FUTURE EVENTS.

Jan. 29—A.C.U. Quarterly Trial, Uxbridge to Banbury and Back.
" 29—Birmingham M.C.C Annual Dinner.
Feb. 18-26—Manchester Motor Cycle Show.
Mar. 12—M.C.C. Opening Run.
" 25—General Meeting of Northern Motor Cycle Clubs at Richmond, Yorks.
" 25—M.C.C. Easter Tour. Jarrott Cup Competition.
" 28—Brooklands A.R C. Easter Meeting
" 30 to April 2—Exhibition of Motor Cycles at Leicester, Association Hall.
Apl. 20—A.C.U. Quarterly Trials.
" 27-28—Brooklands A.R C. Meetings.
" 30—M.C.C. Members' Hill-climb.
May 13, 14, and 16 (Whitsun)—M.C.C. London-Edinburgh and London-Edinburgh and Back Runs.
" 26 (Thursday)—International Motor Cycle Tourist Trophy Race in the Isle of Man.
" 28—A.C.U. Open Hill-climb.

South Manchester M.C.C.

The first annual meeting of this club was held at headquarters, the Denmark Hotel, Greenheys, on the 19th inst. The balance-sheet for 1909 was adopted, and considered very satisfactory. Officers for the year were appointed, and a good programme of competitions and runs was mapped out. It was decided to affiliate with the A.C.U., and the annual subscription was raised to 10s. in order to cover the cost of affiliation.

Mr. R. Fisher was unanimously elected president of the club, and he kindly offered a trophy to be competed for during the year.

It is hoped that the energetic programme and facilities offered by the club will draw a large number of new members, and an invitation is held out to all motor cyclists in the district to communicate with the hon. secretary, Mr. F. Doodson, 15, Eileen Grove, Rusholme, who will be glad to supply any information as to membership.

Birmingham M.C.C.

The seventh annual dinner will be held at the Imperial Hotel, Temple Street, on Saturday next, the 29th inst. This is a special occasion, as it marks the club's attainment to a membership of 100. Ladies are cordially invited. A musical programme is being arranged.

Leith M.C.

The annual general meeting will be held in the Commercial Hotel, Commercial Street, Leith, on the evening of the 28th inst. at eight o'clock, when it is hoped there will be a large attendance of members and prospective members.

The Newcastle M.C.

On Wednesday next a whist drive will be held at the Royal Arcade Assembly Roms. It is hoped that a large number of members will attend and help to make this social event a success and a credit to the club. Tickets are 1s. 6d., including refreshments. The club secretary, Mr. A. G. Robson, 61, High Bridge Street, Newcastle-on-Tyne, will supply tickets.

Coventry and Warwickshire M.C.

The annual dinner has been postponed to early in February, permission not having yet been obtained for the use of St. Mary's Hall.

Members who have changed their addresses are requested to notify the secretary, Mr. E. W. Walford, as several circulars respecting the club have been returned to him undelivered to the addressee.

Ayr and District M.C.

The annual dinner was held in the Hotel Dalblair on Wednesday evening last, and was attended by a large and representative number of members and friends.

Mr. John Houston, the president, occupied the chair, Mr. Alf. Sommerville fulfilled the duties of croupier, and the prizes for last year's events were presented by Mr. W. G. Wallace. An excellent musical programme was provided, and the evening proved most successful.

Club Life.

A NORTHERN clubman wrote last week asking us to obtain the opinions of readers regarding the formation of clubs in large cities and towns solely for middle-aged riders, or, as he puts it, men between forty and fifty years of age. His complaint is that the majority of clubs are formed of active young men mostly bent on speed, and he instances a club which he joined last year, thinking that he was going to obtain pleasant companionship during his rides, and assistance in the way of touring and other matters appertaining to the use of the motor cycle. Whilst we are not of the opinion that clubs are needed with a membership confined to riders of any particular age, it might be advantageous for the executives of clubs which devote a very large portion of the year to competition work to consider whether they would not increase their membership by the inauguration of a touring section, with a sub-committee to deal with the branch of the pastime which particularly appeals to such as our correspondent.

The fact has always been before us that the chief supporters of the pastime are young men, but middle-aged and elderly men are taking up motor cycling in greater numbers every year, and the young enthusiasts of five years ago and to-day will in a few years time be on the *qui vive* for just the kind of easy-going club that our Northern friend is anxious to establish. We do not suggest that ordinary club runs are likely to fascinate even the middle-aged rider, because riding in close company is to be avoided for many reasons, the chief one being the nuisance created by dust; but there are many ways in which a club could be of the greatest assistance to middle-aged riders. By specially catering for them the present clubs could doubtless increase their ranks, but our correspondent thinks that there is room for a club in each large city and town which will be specially devoted to the interests of middle-aged riders who do not want to compete in hill-climbs, races, and other events, but require the companionship of other riders, and assistance and advice in touring matters.

Various Uses of a Motor Cycle.

WE think it is possible that there are some of our readers who would like to discuss this question, and if there is a desire for separate clubs on the lines suggested, we shall be glad to assist in their organisation by publishing in our Club News columns the names and addresses of those who are prepared to take the necessary steps towards their formation. Every motor cyclist regards the pastime from a different viewpoint. Some ride a motor cycle because it takes them over ground which they have not been able to reach previously on a pedal cycle in the duration of a short ride; others combine motor cycling with another pastime, such as riding to golf, tennis, fishing, or boating; but the greater number undoubtedly prefer some form of motor cycle sporting competition. A club is useful to all, and it remains to be seen if there are sufficient riders to support our correspondent's suggestion.

In connection with touring and legal advice, etc., readers should bear in mind that such bodies as the Auto Cycle Union and the Motor Union have special departments to deal with these matters, and are always prepared to assist their members, but they do not cater for local companionship, which our correspondent appears to desire most.

OCCASIONAL COMMENTS

BY "IXION"

A Clear Silencer.

Most motor cyclists are aware in theory that a choked silencer has very detrimental results upon the running of an engine, but I suspect few know by experience what a colossal braking power the back pressure due to choked exhaust orifices can exert. I own an engine which is fitted with a particularly efficient silencer, and for some weeks I was troubled with a gradually increasing loss of power which I could not trace to its origin. Everything was apparently in good order, and yet the engine would not develop any pace. At last things suddenly got so bad that with the levers set for thirty miles an hour the machine was only travelling at the merest crawl. Dismounting I happened to notice a jet of smoke issuing from the silencer in a constant stream though the engine was stopped. I had the silencer to pieces in a trice, and found that the holes in the baffle pieces were ridiculously small, and that the majority of theme were sooted up. Before replacing the exhaust box I had parts of it on the lathe, and drilled out the aforesaid holes. Oddly enough, the machine is still as silent as ever it was when throttled down—as silent as when the holes were clogged, even; but, naturally, the bark is somewhat louder when the engine is speeded up.

When the Plug Soots.

I met one rider who had been over-lubricating, and had endeavoured to cope with the trouble by merely changing his sparking plug, until all his spare plugs were so sooty that none of them would fire. Needless to say, this is a very makeshift method of dealing with a trouble which is rather apt to occur when a slipping belt or prolonged driving on a low gear has compelled the driver to use overmuch oil. If the cylinder is simply swimming with oil, the surplus should be got rid of before fitting a fresh plug. In winter time, when I am none too warm, I should remove the plugs and open the drain tap of the crank case, and then get rid of the oil by five minutes' pedalling on the stand, which would serve the additional purpose of restoring my circulation. In summer I should assist the process by a liberal injection of paraffin, but it is merely silly to soot up a clean plug without removing the cause of the trouble.

Skidding.

I wish I could persuade some of the fair weather brigade to put their fears in their pockets and attempt a little winter riding. There are thousands of motor cyclists who only ride when the roads are good, and they would be astounded if they essayed a little mud-plugging. With a modern machine and a good non-slipping tyre tread skidding is practically non-existent. Looking through my road book I find I have only had two real skids in the last three years, and both of these occurred in summer. Admitting that some care is required in traffic, and especially over tramlines, the side-slip bogey is vastly overdone. To my mind the only real problems of all weather riding are how to keep clean and how to keep warm, the latter being far and away the more difficult. I have been out on the roads the last week or two in all weathers by day and night, and I have met very few motor cyclists; I made a point of conversing with those I met, and they laughed at the idea of road surface dangers—none of them had tumbled this winter. One of them was very well fitted out for the cold weather with handle-bar muffs, three jackets, wading boots, and a cap with earholes guarded by rolls in front of the ears; another had a celluloid wind screen mounted on his handle-bars, and so hinged that it could be folded down when there was no wind; he said it kept him as cosy as if he were on board a car. Several of these machines were fitted with special winter guards of the Miller and Cameron types, and all the riders looked in the pink of health and condition.

The One Dangerous Surface.

There is one surface on which I should advise the most expert and enthusiastic of riders not to risk his neck. I speak feelingly, for I was recently trapped by a change in the weather on a long ride, and had a most fearsome time. It is when a gentle thaw succeeds a layer of snow which has covered the roads for several days. The four or five inches of snow first get trampled hard by a few days of traffic, and the nightly frosts solidify the surface into a coating of hard ice. Then the thaw comes and moistens the surface. If any rider has found tyres which can grip such a surface I shall be glad to hear of them, for I have not. It is true that I did not hurt myself, for I rode at the edge of the road, where the snow was comparatively untrodden until I neared a town, and here my machine turned at right angles, and took me down a side road in which I took not one atom of interest. Deterred by this incident, I got off and walked to the railway station. Rubber studs proved as bad as steel studs were on the last occasion when I was faced by such conditions, and the machine was practically unsteerable.

Tyres in Winter.

I believe the fear of punctures is one of the main deterents to ardent riding in winter, and I must confess there is no more heartrending situation than to be stranded on a lonely road with a tyre to mend when the thermometer is down towards zero. But why risk such a situation? Personally, I always see that my covers are a nice easy fit before I go out in bad weather. If a new cover is to be used I work it on and off the rims several times at home in the warmth of a fire before ever I take it on the road, till at last it can be detached without tools if desired. Then, though I may go out in summer without any butt-enders, I never dream of venturing forth in winter without at least a couple of these invaluable accessories. If a puncture befall me amid the snow or when a bleak east wind howls over the frozen roads I know I can slip a new tube into place within five minutes, and there are no terrors about this operation. Pumping up the new tube will destroy any chilliness incurred in fitting.

BORE-STROKE RATIO & EFFICIENCY.

A REPLY TO A. A. SCOTT'S CRITICISM.

By JAMES L. NORTON, A.M.I.A.E.

I HAVE read with some pleasure Mr. Scott's criticism of my article on "Bore-stroke Ratio and Efficiency," and must confess I am not surprised that the criticism makes out anything but a strong case for the short-stroke engine. In fact, I think it strengthens the case for the long stroke rather than otherwise.

I will consider consecutively the several points of the criticism, the earlier portions of which, however, have no bearing upon the question at issue. Nevertheless, as they tend to place my arguments in a somewhat false light, I think it well to call attention to one or two of them.

Exception is taken to what Mr. Scott terms my extreme comparison. Now the engines I gave for illustration were one 100 mm. bore by 64 mm. stroke, and one of 80 mm. bore and 100 mm. stroke. In the first case the bore is thirty-six per cent. greater than the stroke length, and in the second case the bore equals eighty per cent. of the stroke.

Mr. Scott gives as his illustration engines of 2¾in. bore by 2⅛in. stroke and 2in. bore by 4in. stroke. In the first case the bore is slightly less than thirty per cent. greater than the stroke, and in the second case the bore only equals fifty per cent. of the stroke—the stroke being *double* the bore diameter. Between my two engines there is a stroke difference of thirty-six per cent. Between Mr. Scott's two engines there is a stroke difference of forty-six per cent.—a ten per cent. greater extreme of comparison than mine, to which he takes exception.

Actual and Isothermal Pressures.

Again, Mr. Scott takes me to task for using the word "absolute," but omits to mention that I coupled with it the words "actual pressure," making it clear that the word "absolute" was used in its ordinary colloquial sense. Perhaps it would have been better to have relied upon the word "actual" only. My use of the word "isothermal" is also misconstrued. Surely Mr. Scott does not suggest that the pressure first mentioned is other than isothermal. He says that "isothermal compression does not take place in an ordinary motor cycle engine." I did not say or imply that it did. My use of the word requires no explanation. Mr. Scott's remarks are evidence that he understands fully the use of the term, yet he implies error on my part, and then by his own calculations proves my statements as to pressures to be correct.

Such criticism as this helps no one, and surely implies lack of sound argument.

It is with reluctance that I write this, but I feel compelled, in justice to myself and to the question at issue, to draw attention to what may, by casual readers, be mistaken for sound reasoning against the long-stroke engine.

Upon the matter of thermal efficiency, it is agreed between us that the long stroke is superior, and that it is necessary to run the short stroke at a higher rate of revolution to give equal power.

Mr. Scott says that "the same advantage is gained by adopting the overhead valve type as by increasing the stroke ratio." He appears to be digressing here from the subject matter.

It is hardly germane to this discussion to state that the short-stroke engine with overhead valves is as efficient as a long stroke with side valves. If the short-stroke engine needs the overhead type of valve to equal the long stroke with side valves, what happens if we adopt the overhead type to the long stroke?

I do not propose to follow my critic in his dissertation on the two-stroke engine, to which my article had no reference.

Frictional Loss caused by Piston Rings.

The argument under the heading "Frictional loss caused by piston rings" is misleading. It is acknowledged that the piston ring of large diameter gives greater pressure and friction than the small ring, but it is claimed that the large ring could be made to exert the same pressure and friction as the small one. This assumes that the small one could not or would not be improved, but it stands to reason that if the large ring can be improved, so also could the smaller one in the same proportion.

A similarly misleading argument is brought to bear in regard to piston load. It is said, "As for the extra load on the short-stroke piston, this could be met by proportionately designed bearings." My critic omits to mention that the same applies to both engines, and the fact remains that, whether plain or ball bearings are used, those of the short stroke have to sustain the heavier load, and the long-stroke engine retains the advantage.

To return to the friction of piston rings. It is said "the long stroke has the extra friction of moving its rings through a further distance of 7½in. for every four strokes," but the fact is overlooked that the total frictional and thermal losses of the short stroke are multiplied by the necessity for a higher speed of revolution. The statement that "the long-stroke engine has to develop an extra amount of power" to com-

Bore-stroke Ratio and Efficiency.—

pensate for extra friction is therefore incorrect, as is also that which reads "the friction of the piston against the cylinder walls is scarcely worth taking into account if long connecting rods are used." This is not a negligible friction, and is much greater in the short stroke, with its 355 lbs. piston load and 5.3in. connecting rod, than in the long stroke, with its 188 lbs. load and 10in. connecting rod, even though the angularity of thrust be the same; therefore the alleged "distinct gain in mechanical efficiency" of the short stroke fails to materialise. My critic's conclusions on these points appear to have been arrived at from an entirely assumed set of conditions.

Load on Bearings.

Further, in an attempt to belittle the detrimental effects of the heavier load on short-stroke bearings, it is said "the extra load is only momentarily applied at dead centre." Quite so, but it is at this moment of first application that the effect of friction and consequent loss thereby is greatest. The criticism maintains that "the load on main bearings of the long-stroke engine is increased by the leverage of the longer crank." I cannot agree with this, the contrary being the fact. My critic's own figures and diagram (fig. 4, page 49) show that the actual load on the long-stroke engine is 376 lbs., whilst that on the short stroke is 543 lbs. (355 lbs. piston load × 188 lbs. belt pull)—a difference of 167 lbs. in favour of the long stroke. In other words, he proves the load on the latter is less than seventy per cent. of that on the short-stroke bearings. In fact, in this connection he turns the guns on his own ranks, and the arguments and figures presented to champion the short stroke favour the long stroke.

Again, the belt pull is assumed to increase the main bearing load. On this matter the argument also appears to be based on assumed and not actual conditions, since the combined piston load and belt pull could only be applied (as in his diagram fig. 4) if the engine were horizontal and at equal height, or approximately so, with the upper edge of rear belt rim, or placed head downwards at somewhere near the angle of forty-five degrees if the engine pulley were in the usual position. As a matter of fact, the usual angle of belt pull is such as to *decrease* the main bearing load due to piston thrust, and this to a much greater proportion in the long stroke. This, in my opinion, is another argument against the short stroke.

It is said that, "since revolutions per minute are limited by piston speed, the short stroke can be run at a greater number of revolutions than the long stroke." This statement appears to be generally accepted, but I think it is scarcely correct. I am of opinion that piston speed is limited by strength of materials and power of impulse, and that piston speeds are attainable far in excess of what are required to reach the limit of speed at which a motor cycle can be safely driven. Factors which limit the number of revolutions are: (1) Ingress and egress of the gases, and (2) speed of combustion and expansion, rather than piston inertia.

If this be so, then either type of engine may be run at equal revolutions until the limit speed of induction, expansion, etc., is reached.

Under the heading "Inertia of Parts," it is stated that "a large diameter piston can be made lighter in proportion to its size than a small diameter piston." I would ask for an explanation of this assertion. It appears to me to be incorrect. A smaller piston can safely be made with proportionately thinner top and walls and be of equivalent strength to a larger one, and since it is smaller, shorter, and thinner, the converse of my critic's statement must be correct.

Length and Weight of Connecting Rods.

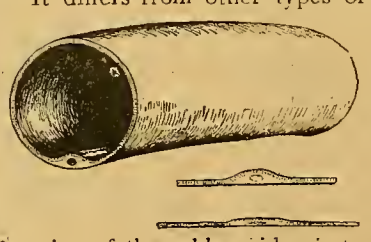
Concerning length and weight of connecting rod—here again assumed conditions form the basis of argument. Even if, for argument sake, the connecting rod for the long-stroke engine is double the length of that of the short stroke, it is by no means necessary that it should be double the weight, for, as has already been shown on both sides, the load on the longer rod is little more than half that on the shorter one.

I feel I must protest once more against my critic's method of reply. On the point of safe piston speed and pressure on cylinder walls, he states, "We have given the same proportion of connecting rod length in both cases"—and just previously he had been criticising the weight of a connecting rod of 10in., but now, in attempting to score a point concerning the pressures, he calmly shortens this rod in order to demonstrate "the additional frictional losses in the long-stroke engine." Now if this shortened rod be considered, then his previous figures concerning the effect of weight on inertia stresses cannot apply. Alternatively, if he were to shorten in the same proportion his 5.3in. connecting rod, would not the additional frictional losses likewise increase in the short-stroke engine?

I have now dealt with the principal points of Mr. Scott's criticism, and shown that his arguments are not favourable to the short-stroke engine, but really serve to strengthen my original case for the long stroke.

ANOTHER REINFORCED INNER TUBE.

THE accompanying illustration is that of a section of a reinforced air tube for motor cycles which has been invented by Mr. F. H. Hall, of the Electric Ignition Co., Ltd., Sampson Road North, Birmingham. It differs from other types of reinforced tubes by having the fabric carried right round the sectional circumference of the tube, and having at the base a moulded rubber portion provided with a cored hole to reduce weight. The function of the rubber ridge is to partially pleat the fabric, so that when the tube is fully inflated the effect is to compress or stretch the rubber portion, and allow the tube to expand to the required extent, the limit of stretch being at a point beyond that at which the outer cover is completely filled by the air tube.



It is claimed for this tube that small punctures are sealed automatically, owing to the rubber being in a state of compression when fully inflated; also that the walls of the tube are of the same strength throughout, owing to the fabric completely encircling the circumference of the section. The tubes, it is said, will stand a pressure of 200 lbs. without bursting when inflated out of the cover. There is therefore no possibility of a burst if the outer cover gets cut.

MOTOR CYCLE RECORDS ACCEPTED IN THE U.S.A.

BELOW is a list of motor cycle records accepted by the Federation of American Motor Cyclists (the governing body of the pastime in America), revised and corrected to January 1st, 1910, by F. L. Valiant. It will be noticed that our American cousins have a separate list of "amateur records," but we may explain that the American amateur definition is very different from the English one. A trade rider is an amateur in America, provided he has never competed for a cash prize. For detailed definition see page 61 last week. We are assured by Dr. J. P. Thornley (chairman of the F.A.M. Competition Committee) that "the records have been made with the greatest care and under the strictest supervision." He adds: "There are no records in the world which have been more carefully gotten up, and every possible factor of error eliminated. It gives me great pleasure to forward this list to you, and the Federation of American Motor Cyclists will greatly appreciate your publishing these records in your valuable journal":

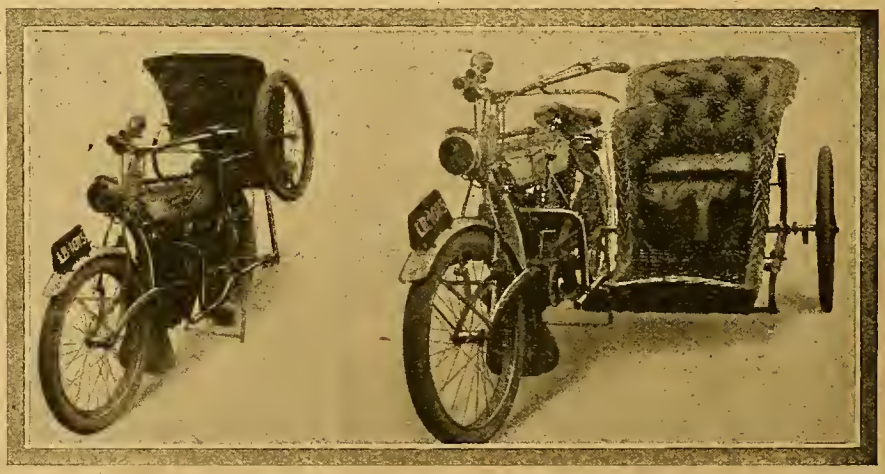
THE HOME GARAGE SIDECAR.

THE Bramson Home Garage Sidecar was fully described in *The Motor Cycle* of November 29th, 1909 (page 940). It is therefore needless to repeat the technical description of this machine, but as we are now enabled to illustrate it, a few points regarding the various advantages it offers will be of interest. From the description referred to above there appears to be a good deal to do to fold up the attachment. This is really not the case, and the whole thing may be folded up in about three minutes. Once folded up, not more than about 25in. of space are taken up laterally, consequently the machine may be wheeled down a narrow passage. Again, though so easily detachable the device is perfectly rigid, the knuckle joints providing the folding arrangements being encased in tubes when the sidecar is ready for the road; consequently these joints are held perfectly tight, and there is nothing whatever to prevent the machine being quite as rigid as the ordinary type of sidecar. Two models are made: Grade B, with one invisible joint without swivel. The wheel of the sidecar is turned up horizontally over the cycle, and held firmly on the luggage-carrier by a special fastener, so held the combination does not take up a space exceeding 27½in. wide. This is sold at a very moderate price. Grade A, with two invisible joints and special swivel to turn the chair round to the luggage-carrier. This closes up to about 26½in., or 23in. when the chair is folded, and costs about £2 more than the aforenamed. For quite a moderate sum any make of sidecar can be converted to fold up in this way. Mr. Bramson, 5, Farleigh Road, Stoke Newington, N., is most confident of the success of his invention, and we must admit that it displays great ingenuity. He is able to deliver these machines expeditiously.



Bramson's folding sidecar fitted to a two-speed V.S.

Next Week.

The Motor Cycle Buyers' Guide, being a complete list of British and foreign motor cycles on the market, together with a full specification of each model.

Benzol as a Fuel.

Mr. W. Gibbons, whose photograph appeared in last week's issue of *The Motor Cycle*, showing him taking a voter to the poll on his Scott and sidecar, informs us that he is using benzol with excellent results.

The First Competition of 1910.

The record entry received for last Saturday's Quarterly Trial bodes well for this year's competitions. The fight for the silver cup for the best aggregate performances in the four Quarterly Trials of 1910 will be keener than ever this year. Next week we hope to give a detailed list of the marks gained by the competitors in Saturday's event.

A Record Holder laid up.

We regret to have to announce that O. C. Godfrey, the holder of the single-cylinder hour record, is laid up in a nursing home in Hampstead with a broken leg. The *fons et origo mali* is not motor cycling, but roller skating—a far more dangerous form of amusement.

Motor Cycle Repairers.

It was recently announced in these pages that the Touring Department of the Royal Automobile Club had decided to officially appoint repairers who make a speciality of motor cycle work. So far only one repairer has been appointed. Motor cyclists who have the interests of their brethren at heart should on finding a repairer who does his work satisfactorily get him to communicate with the secretary of the R.A.C., 119, Piccadilly, and be prepared to vouch for his satisfactory work if called upon to do so. In this way a list of good motor cycle repairers in all parts of the country will be drawn up, and members of the Auto Cycle Union, its affiliated clubs, and others will know to whom to go when they are in trouble on tour. To make the scheme the success it deserves, motor cyclists should endeavour to bring the names of reliable people before the R.A.C. with as little delay as possible.

SPECIAL FEATURES

FIRST QUARTERLY TRIALS OF 1910.

THE 1910 END-TO-END TRIALS ROUTE.

MOTOR CYCLE RECORDS ACCEPTED IN U.S.A.

The Electrically-propelled Bicycle not far off (?)

Edison's wonderful storage battery is once again the subject of newspaper comment. It is said that on a recent trial the batteries propelled a tram-car laden with people quite satisfactorily, and the cost was equal to only one halfpenny per mile. We are promised wonderful things in the way of electrically-propelled bicycles if this much talked of battery ever does materialise.

I.R. Licences issued in 1908.

Licences issued to owners of motor cycles by the Inland Revenue authorities for the year ended December 31st, 1908, totalled 35,784. Of these, 32,355 were taken out in England, and the remainder (3,429) in Scotland. Up to the present, motor cycles used in Ireland have been free of this particular tax, but should the Budget be eventually passed—and there is a possibility that it will—this Irish grievance will be removed!

Sydney Motor Cycle Club's Hill-climb.

In latest advices from "down under" we learn of the victory of F. Flew on a 5 h.p. V.S. in a hill-climb at Dundas on the 18th ult. J. Maguire (2 h.p. Moto-Rêve) was second, and T. W. Verdant (5 h.p. V.S.) third, out of a field of twelve starters. In the eliminating rounds, competitors were despatched in pairs, and the final left the above three, who made one race of it, and finished in the order given.

Mr. Alfred R. Abbott, jun., and his 8 h.p. Matchless and sidecar, which he used on the 21st inst. for carrying voters to the poll at Enfield. The same machine was entered for Saturday's Quarterly Trial, which is described in this week's supplement.

Production of Motor Cycles in 1907.

The first returns made by motor cycle manufacturers of the kingdom to the Board of Trade under the provisions of the Census of Production Act, 1906, have now been issued. The summary shows that during 1907 3,600 motor cycles were made in this country, of the value of £135,000. Of these, 800 were exported, of the value of £28,000. Foreign imports of motor cycles numbered 1,700 complete machines, valued at £48,000. Of course, since 1907 the number of motor cycles produced has very greatly increased.

Local Taxation Licences.

It seems that at present at any rate the authorities have no right to demand that applicants should furnish the registration numbers of their machines on their licence forms. Those who do not wish to comply with this request should, in the event of their application being refused, tender it again in the presence of two witnesses. This is the advice *The Autocar* is giving to its readers.

The German Motor Cyclists' Corps.

By virtue of a compact between the Deutsche Motorfahrer-Vereinigung and the German military authorities, which will be binding on both parties until the end of March, 1911, and subsequently tacitly renewable each year unless notice of annulment be given by either party, a German motor cyclists' corps has at length crystallised into an accomplished fact. Members of the corps will be known officially as "Schnellfahrer," or express orderlies. Over and above the sum of 200 marks to cover cost of clothing, equipment, and underwear, payable on the day when he joins the forces in the event of mobilisation, the "Schnellfahrer" (who must be a healthy German citizen with a clean legal record) receives 13 marks a day, payable in advance each time for a period of ten days. Of this amount, 1 mark covers wear and tear of clothing and underwear, and 2 marks are regarded as extra allowance. The maximum pension of a disabled "Schnellfahrer" can reach 2,544 marks (£127 2s.) per annum. Besides the above-mentioned pay for services, the "Schnellfahrer" get free rations, as well as gratuitous medical treatment. Moreover, the War Office buys his machine at a price estimated by experts as soon as ever he commences service, also supplies him with a pistol or revolver, and bears all expenses of travelling and transport to and from the rider's residence and the place of service.

The Six Days' Trial.

The first entries for the Land's End to John-o'-Groat's Trial in July are three twin-cylinder lightweight Douglas motor cycles.

The Great Paris Flood.

The floods in Paris reached such proportions on Thursday of last week that all the motor factories in the districts of Suresnes and Puteaux had been abandoned with the exception of the Panhard and Levassor, Mors, and Gladiator shops.

Manufacturers Experiencing a Heavy Demand.

Five months for delivery sounds a long way ahead, but we are assured that it is none the less true that a certain firm of motor cycle manufacturers stipulate this time for delivery of their new models, so heavy is the demand.

American Motor Cycle Records.

A list of authentic motor cycle records as recognised by the Federation of American Motor Cyclists is published in this issue. Americans have not claimed all our British riders' records, as we expected they would, but instead they have sub-divided the list into "Amateur" and "Professional" records. There is no such thing as an amateur record in this country at present.

A Champion Tennis Player and Motor Cyclist.

Mr. A. F. Wilding, New Zealand's champion tennis player, is still an ardent motor cyclist, and a rider of a spring-frame Bat. In a recent issue of the *New Zealand Motor and Cycle Journal* he related his experiences on Continental tours and during the Land's End to John-o'-Groat's Run of 1908. In the last-mentioned trial many readers will remember that he gained a gold medal and the special prize for best performance of a private owner.

Racehorse v. Motor Cycle.

The £100 wager referred to in last week's issue is causing quite a stir, and everybody wishes to see the race. The general opinion seems to be that the motor cyclist will win, especially as he has stipulated a flying start.

Three Shows in 1910.

We are in a position to announce that there will be two motor cycle shows this year, the Stanley at the Agricultural Hall November 11th to 19th, and the Cycle and Motor Trades Association Show at Olympia, also in November. There will be, therefore, three weeks of motor and cycle shows in 1910, if, as is likely, the car show at Olympia precedes the Stanley, and the motor cycle and cycle show at Olympia follows the Stanley.

FUTURE EVENTS.

Feb. 18-26—Manchester Motor Cycle Show, City Exhibition Hall, Deansgate.
Mar. 12—M.C.C. Opening Run.
" 16—(Wed.) British Motor Cycle Racing Club Meeting at Brooklands
" 25—General Meeting of Northern Motor Cycle Clubs at Richmond, Yorks.
" 25—M.C.C. Easter Tour. Jarrott Cup Competition.
" 28—Brooklands A.R.C. Easter Meeting.
" 30 to April 2—Exhibition of Motor Cycles at Leicester, Association Hall.
Apl. 13—(Wed.) B.M.C.R.C. Meeting at Brooklands.
" 20—A.C.U. Second Quarterly Trial.
" 27-28—Brooklands A.R.C. Meetings.
" 30—M.C.C. Members' Hill-climb.
May 4—B.M.C.R.C. Meeting at Brooklands.
" 13, 14, and 16 (Whitsun)—M.C.C. London-Edinburgh and London-Edinburgh and Back Runs.
" 26 (Thursday)—International Motor Cycle T.T. Race in the Isle of Man.
" 28—A.C.U. Open Hill-climb.

Free Engine Clutches.

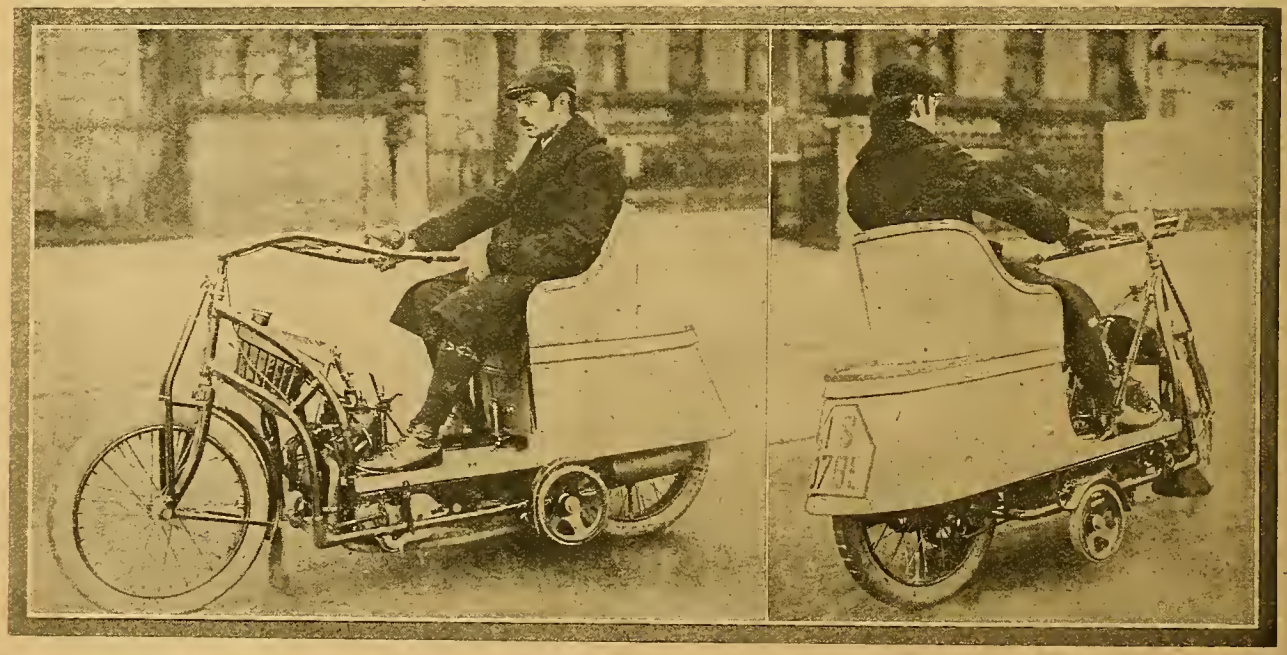
Free engines are quickly gaining popularity in U.S.A. Already it is stated that eleven motor cycle manufacturers have decided to fit a free engine pulley to their 1910 models, and it is known that other manufacturers are experimenting with devices of this nature.

Single and Twin-cylinder Machines in Saturday's Trial.

Of the seventy-four motor cycles entered for the Quarterly Trial on Saturday, thirty-five of the bicycles and the one tricycle were propelled by single-cylinder engines, the other thirty having twin-cylinders. The eight passenger motor cycles were represented by four single and four twin-cylinder machines.

Motor Pace Revival.

The possibility of the N.C.U. recognising and allowing motor pacing in this country seems to be very probable, and there is no doubt that properly regulated this class of racing is very popular with the sporting public, who must be tired of seeing the usual handicaps week after week. It will be remembered that when a good programme, including motor racing and motor pacing, was put on at Canning Town there was always a crowd of ten to fifteen thousand spectators to follow this interesting and exciting form of sport. At the recent meeting of the National Cyclists' Union the thin end of the wedge was introduced by a resolution, which was carried, that in any motor-paced races held in this country the roller must be at least twenty inches behind the back wheel on tracks like Canning Town and the Stadium, etc., and still further back on tracks where the banking is inferior.



The above peculiar design of motor cycle has recently been undergoing tests on the Motmannschen Track, Potsdam. On each side there is an auxiliary rubber-tyred wheel which can be raised or lowered in order to add to the stability of the machine when going slowly or at rest on the lines of the Clissold anti-skid device exhibited at the Stanley Show. The twin-cylinder engine is water-cooled, and the drive is by chain through a change speed gear.

A selection of questions of general interest received from readers and our replies thereto. All queries should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, E.C., and whether intended for publication or not, **must be accompanied by a stamped addressed envelope for reply.**

"Clean" Counties.

Will you kindly inform me of the nearest county to Cambridgeshire that has not done the "donkey work" of motor trapping, as there are several members of our club who wish to take out their licences in such a county?—H.S.W. (Cambridgeshire M.C.C.)

We should recommend you and your fellow members to renew licences in Bedfordshire, as, so far as we are aware, there have been no police traps in that shire up to the present.

Rubber and Canvas v. Leather Belts.

For real flexibility, which is better, a rubber and canvas or a leather belt? I want the most suitable belt for my 2½ h.p. Matchless, which has rather small pulleys. A ¾in. rubber went to bits in two or three hundred miles. I am thinking of getting a Watawata. I understand that leather belts require a lot of attention, and are much harder on the pulleys than rubber belts. Is this so?—C. S. J.

You might well try the Watawata belt mentioned in your query. It would probably be the most suitable for your purpose. We have personally proved it to be especially good in cases where a small pulley is used. A leather belt certainly does need more attention than a rubber belt to keep it in first-class order, but, on the other hand, it will usually outlast the rubber and canvas variety.

Taking a Passenger on the Carrier.

Am I injuring my 1909 3½ h.p. machine by sometimes taking a passenger behind on the carrier? My weight, including top coat and suit case with spares on carrier, is fifteen stones, my occasional passenger, say, from ten to twelve stones? The machine flies up hills round Edinburgh in a marvellous way, but my friends say I ought to be summoned for cruelty to motor bicycles. But am I injuring the machine in any way?—R.W.

We do not think you are doing any particular harm by taking a passenger occasionally on the carrier, although you are imposing strains which the machine was not designed to withstand. It is not advisable to make a practice of carrying an extra passenger, but if you particularly desire to do so, we should recommend you to consult the makers of your machine as to fitting stronger wheel spindles.

A Route from the Midlands.

Please tell me the best route for motor cycle and sidecar from Worcester to Tunbridge Wells. I suppose that I shall not encounter any hills too severe for a 5½ h.p. twin with two-speed gear?—A.J.H.T.

Your best route would be as follows: Worcester, Evesham, Moreton-in-the-Marsh, Chipping Norton, Woodstock, Oxford, Henley, Windsor, Chertsey, Guildford, Cranleigh, Horsham, Crawley, Three Bridges, East Grinstead, and Tunbridge Wells. There are no hills on the route which a 5½ h.p. two-speed twin should not easily ascend.

Single and Twin Cylinders Compared.

Would the Douglas lightweight suit me? My weight is 9 stones, and I want a machine which would take me and a push bicycle coupled. Of course, I should expect to have to pedal a little up steep hills, and there are several in this neighbourhood (Surrey). Also is the cost of running a twin-cylinder machine more than a single? What are the advantages of a twin over a single?—H. P.

We should say that the machine in question would suit you admirably. Of course, there would not be much power in reserve when taking a passenger, but you would get along all right in fairly level country. The machine would cost no more to run than a single-cylinder of equal power. The advantages of a twin are smoother running and absence of vibration, and also quicker acceleration.

Skidding of Rear Wheel.

In attempting to start my twin-cylinder Kerry motor cycle the back wheel pulls up on compression, and will often do so after firing three or four times regularly. I believe the cylinders have been rebored. Compression is good. Do you think it is too good? Carburetter will take no extra air at all. I do not think it is a case of misfiring, but it simply skids the back wheel. It is just the same whether ignition be advanced or retarded for starting. The engine will not run at slow speeds.—H.F.P.

The trouble is most likely due to the adjustment of the carburetter. Evidently too small a jet is fitted. The fact that the machine starts with great difficulty and admits no extra air seems to indicate that this is what is the matter. The compression cannot be too good. The symptoms you describe would be due to pre-ignition, probably from starting with the spark too far advanced, thus causing a back fire. As a last resource we should suspect that the timing had shifted itself.

Notice of Change of Ownership.

Is a person (not a dealer in cycles or cars) required by law on selling his motor cycle to give notice to the authority in the town or county in which it was registered, and if so, is he under a penalty for not doing so? Or is it the duty of the buyer only to have those numbers transferred to his name or re-register altogether?—W.J.P.

According to the Act, either the old or the new owner may notify the authorities of the change of ownership. It is generally understood, however, that it is the new owner's duty to notify the authorities of the change of ownership, and to ask for the numbers to be transferred to his name, the registration being of the particular machine and not of the owner. In case of doubt, it is advisable for the seller to advise the authorities that he is no longer the owner of the motor cycle bearing the particular numbers.

Sidecar Attachments.

I am purchasing a 1910 Triumph fitted with their patent free engine. Would this pull a sidecar and passenger without undue strain to the machine and climb reasonable hills, geared at 5 to 1? Also what do you consider should be the maximum weight of passenger, my own weight being eleven stones? Your answer being "yes" to above, what do you consider the best type of sidecar?—J.H.

The machine in question should be suitable for sidecar work with a passenger not exceeding nine stones in weight, but it would be better still if you had a two-speed gear fitted, as frequently in touring you would encounter hills which could not be climbed with a single gear. Good sidecars suitable for your purpose are made by Messrs. W. Montgomery and Co., and Messrs. Mills and Fulford, both of Coventry, and Messrs. the Chater Lea Mfg. Co., Ltd., 116, Golden Lane, E.C. There is no best "type," but the rigid pattern seems to be the most generally favoured.

Examining a Second-hand Motor Bicycle.

I am thinking of buying a lightweight motor bicycle, and should be very much obliged if you could give me some information on the following points: (1.) In examining several second-hand machines offered for sale I have found the pulley rather loose. Is this usual, or does it show excessive wear? (2.) Would a 1¾ h.p. to 2 h.p. machine be capable of carrying me up all the hills on the London-Hastings and London-Portsmouth roads without pedal assistance, my weight being nine stones? (3.) Is it possible to get a reliable magneto machine of this description for about £16 or £18? (4.) How is it possible to tell if the bearings are worn on a motor bicycle?—J. L.

(1.) The looseness of the pulley seems to indicate that the bearing is worn. (2.) Yes, if in good condition a 2 h.p. lightweight would do what you require. (3.) You have stated a somewhat low figure. At this time of the year it is doubtful if you would obtain a low-powered magneto machine in really good order under £20 or so. (4.) Move the pulley up and down vertically. If there is play it is a sure indication that the bearing is worn. You can only tell if all the bearings in the engine are worn by removing the cylinder, although it is usually possible to get an idea by pedalling the engine round on the stand with the exhaust valve lifted. A rumbling or a faint knocking is a sure sign of worn bearings.

READERS' REPLIES.

The Effect of Fitting a New Piston.

In *The Motor Cycle* of January 10th I noticed a query respecting a 2¾ h.p. Humber engine (1904). Some time ago I possessed one of the same make, and had a dome top piston fitted with rings at top and bottom; this affected the lubrication on mine. On top of the crank case there was a projecting ring standing above the level of the baffle plate, and after sawing this off I gained perfect lubrication. The new piston was larger and decidedly heavier than the old one. I could climb practically anything I came across with a single gear of 6 to 1. If "F. A. C." cannot find any other remedy, I should advise him to try this, removing the above-mentioned ring, and to leave the piston alone. It worked admirably in my case.—D. F. AUSTIN.

Adjustable Pulleys and Tightening Belts.

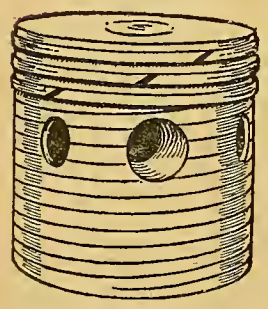
I have several times noticed correspondents advised in these columns to use the adjustable pulley for taking up slack in the belt. This is surely an extremely cumbersome way compared with the use of extra hooks in the belt fastener, for instance Stanley Webb's hooks. With these the shortening of the belt is literally the matter of a few seconds, besides doing away with the disadvantage of running on a higher gear than is wished for. By keeping an eye on the belt and shortening it at home when it shows signs of pulling through, and at the same time inserting a hook, belt troubles on the road can be practically eliminated. In my case pulling through never occurs.—FCH 24.

Loss of Power.

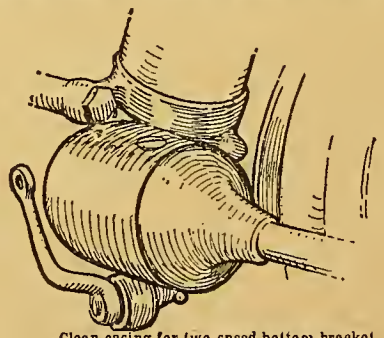
A similar trouble occurred to my machine two years ago. The writer "W.C.B." does not say if he has given attention to the silencer of his machine. The holes in some silencers are very minute, and easily clogged, especially if the engine be somewhat over-lubricated. If the silencer is an intricate one the trouble may be made much less frequent if some of the inner parts are removed; there is then practically no difference in the noise of the exhaust, and back pressure is not so great. The best way to clean a silencer is to take it to pieces, and to heat each part red hot in a coke stove or in the flame of a powerful blast lamp. After the parts have cooled an easy brushing in cold water will clean it as new.—A.E.M.

SOME FEATURES OF AMERICAN MOTOR CYCLE DESIGN.

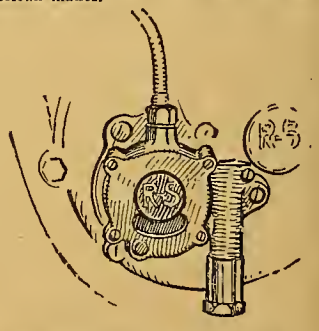
Motor cycles exhibited at the recent New York Show were of much improved design. The Indian (the features of which are already well known to our readers) is still an easy winner, but we illustrate some of the best points of other American makes.



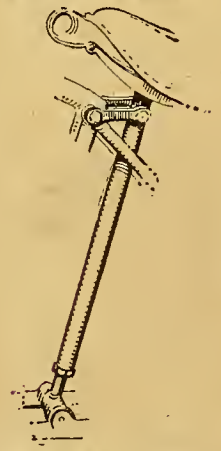
Lubricating channels and holes in Curtiss-marve. piston.



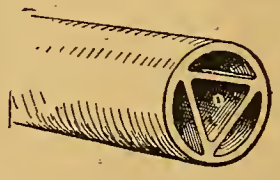
Clean casing for two-speed bottom bracket gear on four-cylinder Pierce.



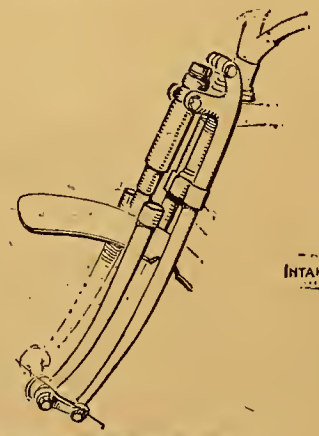
R.S. mechanical oiler operated by the exhaust cam.



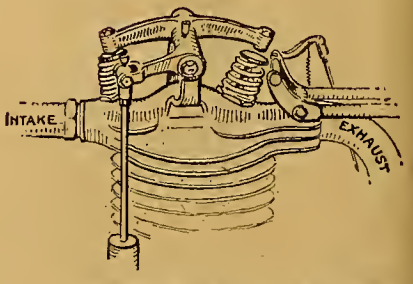
Neat type of spring seat pillar on the Greyhound. Maximum spring compression, 1½in.



Triangular reinforcement of Emblem frame tube.



Semi-pneumatic spring fork on the Greyhound. Ball bearing rockers.



Overhead valves of the new Curtiss engine, mechanically operated by one rod.

[*From "Motor Cycling" of Chicago, U.S.A.*]

The 1910 End to End Trials Route

FIRST AND LAST HOUSE, LAND'S END.

QUITE recently we published in *The Motor Cycle* a map of the amended Land's End to John-o'-Groat's route, together with a few brief notes on the alterations decided upon by the A.C.U. committee. It may appear to some of our readers that it is a pity to depart from the classical route followed by record breakers on bicycles and motor bicycles from the time of the Hon. Ion Keith-Falconer to Mr. Ivan B. Hart Davies, but it must be remembered that the object of the Land's End to John-o'-Groat's Six Days' Trial is not to encourage record breaking, but to prove the reliability of the motor cycle by taking the machines over the longest possible route from one end of the country to the other, and at the same time by choosing a severe course to test the machines to the utmost.

Start from Penzance.

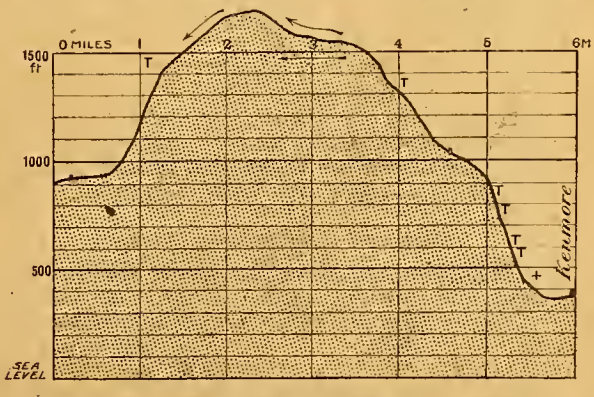
On the Monday morning the trial starts from Penzance, whence the competitors proceed to the Land's End Hotel, and here they are assembled to start together on their long journey north. Taunton is reached the first night after a somewhat difficult day's run. Next follows a long journey on the Tuesday morning from Taunton to Warrington. In the early part of the day, as far as Bristol, the road is hilly, but after that the run is comparatively easy and over good roads to Kidderminster, where, after leaving the town, there are a couple of stiff ascents, which usually attract a number of spectators from various parts of the kingdom. Once these hills are climbed all is plain sailing, and over magnificent roads the busy town of Warrington is reached. Unfortunately, here the accommodation is somewhat limited, but there is some consolation in knowing that it is one of the only two places on the route where the men may experience trouble in securing suitable accommodation.

The early part of Wednesday morning is occupied in threading through Wigan, Preston, Lancaster, and suchlike thickly populated towns with badly paved streets, relieved, fortunately, at intervals by stretches of good road which connect them.

The Climb over Shap Fell.

After Lancaster comes Kendal, and then there is the magnificent climb over Shap Fell, not very formidable in these days to the modern up-to-date motor bicycle. From Penrith to Carlisle the road is magnificent, but, unfortunately, traps are rather prevalent in this part of the country. After Carlisle the border is crossed at Gretna Green, a tiny village of white-washed houses memorable for the famous blacksmith's shop where so many happy runaway couples were united in times gone by. So far the route has not been altered, but since Scotland is new country to many of the competitors, we propose to deal more fully with this portion of the route. From Gretna Green on through Ecclefechan (the first of the difficult Scotch names to pronounce) we pass through Lockerbie, and at Beattock leave the road for about one and a half miles, and enter the pretty Lowland town of Moffat, where the night is spent.

On the Thursday morning we leave Moffat by a side road, and again join the main road to Glasgow, climbing the beautifully graded and excellently made road over Beattock Summit, alongside of which the Caledonian Railway runs, up which snorting trains laboriously pant their way to the North. Not so the motor bicycles, which fly like things of life on their long journey. Beattock Summit is 1,028 feet above sea level, the highest altitude hitherto reached. The going is quite good all the way from Abington Inn to Lanark, but from Lanark to a point just short of Airdrie we pass through the manufacturing district lying twixt Glasgow and Edinburgh. Once this is over there is nothing but the great and glorious country, free of big towns, paved roads, and greasy tramlines,



Contour section of Amu'ree. End-to-end competitors will climb (?) the northern side from Kenmore.

From the Contour Road Book, printed by arrangement with Messrs Gall & Inglis.

A23

The 1910 End-to-end Trials Route.—

extending right up to the most northern point of Great Britain.

Nearing Stirling, we pass the Field of Bannockburn, and eventually reach the town, where lunch is taken. Stirling, replete with historical memories of Robert Bruce, may justly be called "the gate of the Highlands." After lunch we enter almost directly into this glorious district. Passing through Thornhill, we traverse an easy road to Callander, immediately after which we enter the Pass of Leny. The road then winds along the first loch to be encountered, the pretty Loch Lubnaig, from which is afforded a fine view of the precipitous heights of Ben Ledi. Next we pass through Strathyre and Kingshouse, familiar to the readers of Scott's "Lady of the Lake," while beyond, if the day is fine, there is an excellent view of Ben More and Ben Stobinian. Next we come to the village of Lochearnhead at the head of Loch Earn, and then climb Glen Ogle, a splendidly engineered road, for which the famous General Wade is responsible. The surface is good, the gradients are excellent, and neither wind nor snow seem to leave lasting imprints upon it. Of it it is said, "Had you seen this road before it was made, you would lift up your hands and bless General Wade." The famous general seems to have been a splendid road-maker. His is the famous classical road leading from Pitlochry to Dunkeld and over the Grampians to Inverness, part of which is to be traversed on the morrow.

Callander from the bridge, showing Ben Ledi in the background.

A Beautiful Stretch of Road.

Leaving Glen Ogle, we descend the valley, turn to the right, and, just missing the village of Killin, skirt Loch Tay. Just before striking the loch we reach the Fall of Dochart. On an island under the bridge over the falls is the burial ground of the MacNabs—a powerful clan, at one time owners of the whole countryside. The next section of road to be covered is particularly beautiful, passing as it does along the picturesque shores of the loch. The road here has a fair surface, but it is very undulating, though none of the gradients seem to be much worse than 1 in 12. Kenmore, which we skirt, lies at the head of Loch Tay, and is a model Highland village. Were it possible to look back, a magnificent view would unfold itself. On the right rises the rugged slopes of Ben Lawers, and at the end of the loch we could see the bold mountain peaks of Ben More and Ben Stobinian. On an islet lying close to the shores of the loch are the ruins of a priory. According to good authority, Sybylla, wife of Alexander I. of Scotland and daughter of Henry I. of England, is buried here.

Almost immediately after skirting Kenmore we turn sharp to the right, and here a precipitous hill meets the riders. Just behind where we turn is the entrance to the grounds of Taymouth Castle, the seat of the Marquis of Breadalbane. The road here is 350ft. above sea level, and in three and a half miles it ascends to over 1,700ft. According to Gall and Inglis's "Contour Road Book," we have now to traverse a precipitous gradient of between 1 in 7 and 1 in 8, with numerous corners, and, according to our authority, impracticable for general purposes. This does not, however, infer that the modern motor bicycle cannot make a clean ascent of it. It is just the hill one would strike off the beaten track in search of such scenery as is not vouchsafed to the ordinary tourist. Once on the summit the competitors will doubtless be glad to rest and gaze around them, when, if the day be fine, a striking view meets the eye. Behind lies Loch Tay, with Ben Lawers dominating the surrounding hills. To the left and right the bleak moorlands, and away to the far north rise the mountain peaks of Schiehallion and the rest of the Grampian Mountains. Having said good-bye to the timekeeper, we shortly descend a precipitous hill, which must be negotiated with the greatest possible care, for we are about to pass over the road up which the Edinburgh M.C.C. held its trials last year. Once round the

The 1910 End-to-end Trials Route.—

dangerous corner, our troubles are at an end, and, passing Amulree Hotel, we take the first turning to the left and ascend Glen Cochill, and proceed to Aberfeldy. Turning to the right and passing Grandtully Castle, we take the first turning on the left, and, crossing the River Tay, which is said to carry more water into the sea than any other river in Scotland, we come to Ballinluig just where the Tay and Tummel join forces. Here we join the old route to the North, and after a final spin of five miles reach Pitlochry, our stopping place for the night.

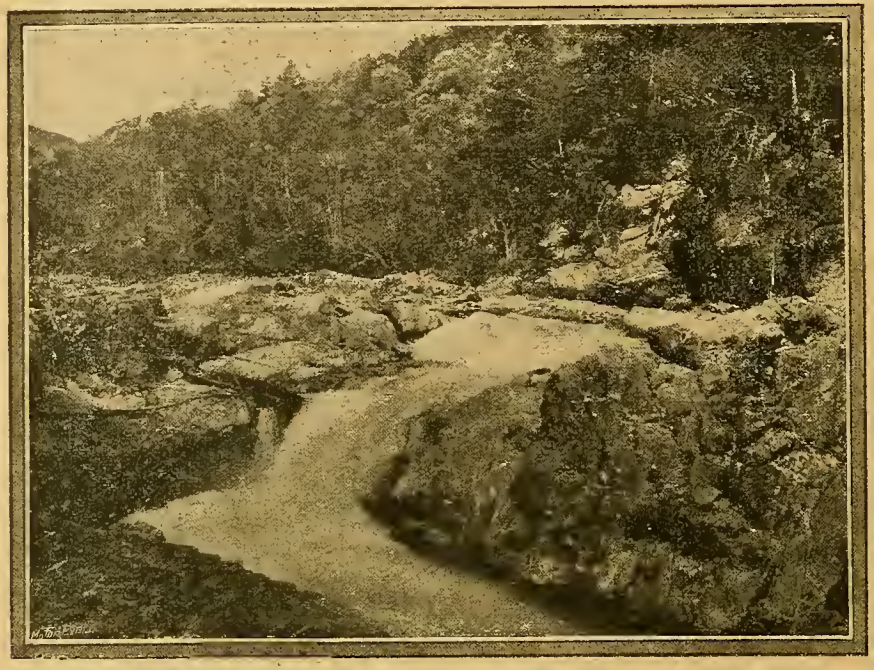
On Friday morning, leaving the famous Highland village of Pitlochry, we traverse the bumpy, tree-shaded road through the Killiecrankie Pass, and, traversing Blair Atholl, enter into the somewhat dreary country which leads over the Drummochter Pass. We pass the Falls of Bruar on the right, of which just a glimpse may be seen, and then the climb begins in earnest. After Struan Station we rapidly leave the tree line, and gradually ascend the last of General Wade's well-graded roads, which was made by him during the Highland Rebellion. All along the route the single line Highland Railway follows, and just past Dalnaspidal Station we reach the summit, 1,500ft. Just before leaving the station there is rather a pretty glimpse of Loch Garry on the left. We then rapidly descend, and, passing Loch Ericht Hotel, enter Dalwhinnie, and, still following the old route, continue our descent to Newtonmore. In 1906, when the trial was first organised, people spoke of Drummochter Pass with bated breath, but the modern machine fears little the long but rather rough ascent, the surface of which leaves much to be desired. At Newtonmore we turn sharp to the left and again enter new country, and there follows a very pretty run through a wooded valley and past Cluny Castle to Laggan, shortly after which we strike the shores of Loch Laggan—a pretty loch—alongside which the route winds. On the opposite side we have a fine view of Sir John Ramsey's Highland home, Ardverikie. Skirting the foot of Ben Alder, we have ten miles of rather dreary country to travel, and then Ben Nevis, the highest mountain in the British Isles, comes into sight, when, if the day be fine, it will be an imposing sight. It is not generally known that Ben Nevis possesses a small glacier, which is the only place in the British Isles where the snow never melts. At Spean Bridge we turn to the right, and after about three miles strike the shores of Loch Lochy, the first of the chain of lochs which form the Caledonian Canal.

Beautiful Loch Lubnaig, alongside which the competitors ride on the fourth day of the End-to-end Trial. The loch is situated between Callander and Killin.

From here onwards the scenery is delightful. The shores of the lochs are wooded, and above them rise the high mountains, while the going is not at all bad. At the end of the loch we turn to the left, and pass Loch Oich on the opposite side, crossing the River Garry as it comes tumbling over tremendous rocks, and through Glengarry, on a rugged headland called Creagan Fhithich (the war-cry of the MacDonalds of Glengarry), where stand the ruins of the castle, long the domain of the chiefs of the clan. Here Prince Charlie slept the night after Culloden, and a few days afterwards it was laid in ruins by the Duke of Cumberland. Seven and a half miles on we reach Fort Augustus, where lunch awaits the hungry competitors. The fort which gives its name to the town was erected

The 1910 End-to-end Trials Route.—

on the suppression of the Jacobites in 1715, and of this powerful fortress nothing is left save the dark, weed-clad walls, the military well, and the grass-grown moat. In 1867 it was sold to Lord Lovat, whose son presented it to the Benedictine Order of Monks for the erection of a monastery on the site.



Falls of the Tommel, near Pitlochry.

Leaving Fort Augustus, we skirt the shores of Loch Ness, and a very beautiful ride it is. On a promontory at the mouth of the Glen Urquhart stands the ruins of the ancient castle of that name, built in the twelfth century, and the scene of a fierce conflict between Edward I. and the Scots in 1303. We now turn inland, and, crossing the River Enrick, which tumbles beneath the bridges, we turn sharp to the left, leave the loch, and ascend Glen Urquhart, continuing along until Invercannich is reached, where the scenery is magnificent. Here we turn right, and, descending Strathglass, pass just south of Beauly, along the shores of Beauly Firth, traversing thirteen miles of the route which we cover the next day. At the end of the Firth we reach Inverness.

The Sixth and Last Day's Run.

After a comfortable night at Inverness, the men will start round the beautiful Beauly Firth, with a fine view of Ben Wyvis in the distance. After about five or six miles the road strikes inland under the railway bridge. Turning to the right, the men ride due north through Beauly to Dingwall. Cromarty Firth is then struck, and there is a fine run from here over a good road along its shores to Alness. Hence there is a road across the hills, but it would have cut the course too short to have adopted it. However, some of the official cars may care to take this short cut to avoid Invergordon. Approaching the latter town, there is a fine view of the Firth, where the water is deep and the outlet is narrow—a splendid anchorage for the Home Fleet. Passing through Tain, we again strike the water—this time Dornoch Firth—and after about three miles a beautiful view of the Firth is obtained. Blue water, wooded shores, and distant mountains lend enchantment to the scene. At the end of the Firth we turn to the right over Bonar Bridge and sharp to the right again, climbing steadily upwards, with a fine view of the Firth on the right through the trees. Shortly after Clashmore Inn we turn to the right, and reach Dornoch, on the coast, for lunch. Leaving Dornoch, we turn to the right at the station, and reach Golspie, immediately after which we pass Dunrobin Castle, the seat of the Duke of Sutherland, president of the R.A.C. On through Brora and Helmsdale to the foot of the Ord, where we rise from 61ft. to 631ft. above sea level.

Descending from the summit down a dangerous hill, we drop into the picturesque village of Berriedale, turn round a sharp corner to the right, and ascend the famous hill, where we have to negotiate a hairpin bend half-way up. From this bend there is a glorious view of the Valley of Berriedale Water, dominated by a fine mountain peak and of the turrets of Langwell House (the Duke of Portland's shooting lodge) nestling in the valley. From here the road is good, and there is not much of interest until Wick is reached. Riding straight through Wick and turning to the left at the end of the town, we enter upon the last seventeen miles of our journey. Passing Keiss, we bear to the right over a moorland road, ascend a short hill, and lo! before us lies Pentland Firth, with the blue sea studded with the picturesque Orkney Islands, while on the edge of the water lies John-o'-Groat's house, our destination, 998 miles from Land's End by the route we have come.

Berriedale, the final test of hill-climbing before John-o'-Groat's House is reached.

From the Contour Road Book, printed by arrangement with Messrs. Gall & Inglis

Altogether the Land's End to John-o'-Groat's route this year offers increased attractions, and it is to be sincerely hoped that it will be well supported.

In compiling this article we have to acknowledge considerable assistance derived from a souvenir of the Scottish Reliability Trials, 1909, by J. Inglis Ker, published by *The Motor World*.

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, E.C., and should be accompanied by the writer's full name and address.

Back-rests for Motor Cyclists.

[4532.]—Some years ago on my old F.D. Werner I noticed the stiffness complained of after seventy or eighty miles, and put it down to the horizontal vibration caused by the engine impulses, which is not provided for in the usual form of saddle spring. On my next machine the saddle was dispensed with and a seat substituted which was insulated from vibration in any direction. On this I have on many occasions made all day journeys, but have never experienced the slightest stiffness since using it.

T. FREDERICK HUNT.

Suggested Improvements to Speedometers.

[4533.]—The speed limit at which motors may travel on the King's highway has been fixed by law at 20 m.p.h., yet motor speedometers are made to register up to 60 m.p.h. As the higher indications of speed are useless to the average motorist as well as to the strictly law-abiding traveller, may I suggest the desirability of placing speedometers on the market showing a range of speed, say, from 3 to 30 m.p.h., that range to occupy the same space now filled by the zero to 60 m.p.h. indicator. The smaller units of speed would therefore be more easily ascertained. One of the speedometers now on the market only indicates from 10 m.p.h.

May I suggest that the best type of indicator *i.e.*, that on which the changes of speed are most easily read, is that in which the centre from which the indicating needle works is not coincident with the centre of the dial, but is at the base of the same.

(Rev.) JOHN HODGKIN.

A Cure for Puncture Troubles.

[4534.]—In reference to Mr. Barnes's recent remark about the puncture-curing compound Miraculum, I may say that I have tried it, and have not been altogether satisfied with it. It seems to me that on a push bicycle, where one's chief enemies are thorns, and similar small things, it would fulfil its purpose very well, and would easily seal up the holes made. But on a motor cycle the matter is different, as one usually gets a much larger puncture than on a push cycle, and it stands to reason that a sort of thick paste couldn't properly seal up a fairly large hole. Also I find that when one is putting on a patch on the roadside the paste oozes out and becomes a terrible nuisance. Also when patch is on it has a tendency to lift it. The best way to avoid the puncture fiend is to have a pair of really good heavy tyres.

PETROLIA.

The 1910 End-to-end Trials Route.

[4535.]—I think it a splendid idea to vary the End-to-end route, as announced in *The Motor Cycle*. Having traversed the exact route last summer from Stirling with motor cycle and sidecar, *viâ* Callander, Killin, Aberfeldy, on to Pitlochry, I found it much more difficult than the old route *viâ* Dunkeld. The road from Stirling has a very bad surface as far as Lochearnhead, and would undoubtedly find out any weak spots in the machines. We found this road much more difficult to traverse than the road onwards over the Drummochter Pass to Newtonmore.

It is a pity the run should take place so early. The latter end of July or beginning of August, in my opinion, would be far better, August being generally recognised as the holiday month. The writer for one could not manage it so early, and would suggest a vote being taken as to which of the dates (the beginning of July, latter end of July, or beginning of August) would be most suitable for the competitors.

BH 619.

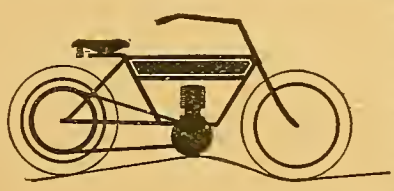
Belts on Lightweights.

[4536.]—Mr. Harry Sharpe in his recent letter states that "weather has made no difference" in his experience of the Motosacoche lightweight. I should be glad if Mr. Sharpe would inform us if the round twisted belt slips when a deluge of an English or Irish shower comes on. Does not the belt refuse to grip and carry him and machine up hills?

E. McQUADE.

Motor Cycle Conditions in the Australian Bush.

[4537.]—I am a constant and interested reader of *The Motor Cycle*, and have been a rider until lately, but my machine is at present "hung up" with a damaged crankcase. Manufacturers seem to strive to make their machines with engines as low as possible—the very feature which unsuits most motor cycles for country use in Australia. Some manufacturers have absolutely declined to fit their engines more than 5in. off the ground to my order, therefore my machine is damaged by contact with the ground. In uneven places if we knew the engine would clear the ground we could ride over the obstructions at eight miles an hour or more, but, being in doubt, we slow right up or dismount, often to find the machine would have just cleared. In some places where the obstruction looks easily surmountable the engine hits. I speak of little gullies or ruts (drains), or perhaps when descending a country hill there are a series of ledges (see sketch).



Now, on our country roads places such as these (maybe a drain, or, as we call them, "gutters," or a ledge of rock) occur on an average every hundred yards. In a day's run, the low-engined machine, even if high-powered, would be completely lost by a light strong one with engine well off the ground. In excessive dust the belt would be smothered, and would not grip at all. The light one could often leave the dusty road, and, in any case, would not be affected. In stormy weather, when a creek may be running knee deep or less, the heavy low-engined machine would have to remain on the bank a day or two till the water subsided, or else be wheeled through—no easy task. After immersion, the whole engine would have to be taken to pieces to get the water out, and if the magneto were fitted low down it would be damaged. The small machine could be carried across with less exertion.

Thanks to the A.C.U. Six Days' Trials, we of the "never, never country" who have not the chance of seeing a Stanley Show and choosing a machine, can find out that small-powered machines are to be had such as I describe. For instance, the Moto-Rêve came through without loss of marks for "reliability." (See *The Motor Cycle* July 14th and August 11th, 1909.) This is the machine whose performances I have been watching and find to answer my requirements. I hope soon to put it to a test in this back country.

I am fully aware that I am writing purely from a bushman's point of view, and am aware that the type of machine I require is in a minority, but surely a percentage of customers appreciate it when we consider South Africa, Australia, and similar places.

Adavale, Q., Australia. A. D. SKINNER.

Licences for Motor Cycles.

[4538.]—Postmaster's recommendation to us to renew our licences in Staffordshire, as it is a county favourable to motor cyclists, is a mistake. Prosecutions have been far too frequent in this district (Stoke). The police hitherto have proved most unmerciful, and as a silent protest I took out my licence in Carlisle, where the police have proved merciful and considerate in the use of the power entrusted to them.

TRENTHAM.

[4539.]—I was pleased to note in your paper of January 17th motorists' consideration *re* taking out licences in counties where fair play is shown by the chief constables. I am taking my licence out this year in Staffordshire, although residing at Muswell Hill.

I should like to suggest that motorists bar Barmouth, not only in licences, but in every other respect. Last year, whilst riding from Harlech to London, as I neared Barmouth an officious member of the force suddenly appeared with a stop-watch, and declared I was travelling to the danger of the public, which, by the way, consisted of himself, and he was hiding behind a cottage wall until I appeared. I was travelling at the time on a tricar at fifteen miles an hour, which I was able to prove by the distance I had travelled since I last stopped. In due course I received a summons, and after an appeal against this gross injustice I had to pay £5 4s. 6d., and my licence was endorsed. A Welshman, in course of conversation, told me that when the roads wanted repairing this was the practice the authorities indulged in. I sent for a Barmouth paper, and was interested to find that five other motorists had been fleeced on the same afternoon.

G. P. HOWE.

Cost of Petrol in Ceylon.

[4540.]—With reference to letter from Mr. Harold North *re* above in a recent issue, will he please say where in Colombo petrol can be bought at under Rs. 1.75? I cannot get it under 1.75. I told the managers of Walker's garage of Mr. North's letter, and they assured me that he paid them Rs. 1.75 per gallon, and that the retail price is fixed at that by Forsyth's, the suppliers.

I am just here for a month with my motor cycle, but hope to have a fortnight here in April, so shall be glad to know where to get cheaper petrol. Colombo is the dearest port in Asia for petrol. The following are the prices I have paid: Bombay 1s. 6d., Calcutta 1s. 6d., Rangoon 1s. 2d., Madras 1s. 6d., Penang 1s. 9d., Singapore 1s. 4½d., Bangkok, Siam 1s. 6½d., Hong Kong 1s. 6d., Shanghai 1s. 1½d., Tientsin 1s. 8½d., and Tokio 1s. 9d. So you see that Colombo at 2s. 4d., even with the rebate of 4d. per gallon (which a non-resident cannot get), is much too high. Then the toll bars every ten miles or so in Ceylon run away with a lot of money. Repairs I know nothing about, as I have not had to have any done here, thank goodness.

Colombo. LEWIS PECK.

Increase of Speed on Partially Raising the Exhaust Valve.

[4541.]—I notice in letter 4506 a reference to the increased speed of petrol engines on slightly raising the exhaust valve. In my experience this only takes place when running slowly with the throttle nearly closed. It is obvious that the action of the throttle is to increase the vacuum in the inlet pipe on suction stroke, so attenuating the charge and reducing the compression. Therefore I do not consider that partial compression relief is likely to provide the solution of this phenomenon, even supposing that a loss of energy on both compression and firing strokes could possibly increase speed.

To my mind, the only feasible suggestion yet put forward was one published in *The Motor Cycle* some time ago, namely, that the pressure of one's fingers on the lever reduced the thrust of exhaust valve springs to a suitable value for the low speed of engine, so reducing the work necessary to lift the valve, and increasing the speed of the engine.

I think few people realise the resistance of the usual type of valve gear with a strong spring and pressure on top of valve. Moreover, the cam is so cut that hardly any of this work is returned when valve closes. The only necessity for a strong spring is to ensure rapid and accurate closing at high speed, so that when a pressure is put on hand lever at slow speeds the valve is easier lifted, the elasticity of the fingers enabling the pressure to follow up valve when it is first started by the cam, which is the period when greatest resistance occurs, due to slope of cam and pressure on valve head. Yet the valve is seated accurately and quickly enough for the slow speed of engine.

I must apologise for the length of this letter, but the subject is one of great interest to me, and I should like to see it thoroughly threshed out. Best wishes for your excellent paper.

J. R. B. KENNEDY.

P.S.—If the above explanation is right, the Indians should be singularly free from this phenomenon; perhaps Mr. Wells will tell us his experience.

Bore-stroke Ratio and Efficiency.

[4542.]—I have read with interest Mr. A. A. Scott's article on "Bore-stroke Ratio and Efficiency" in the last issue, and cordially agree with most of his conclusions, but I think he does not make quite enough of the loss of power due to exposed surface in the combustion chamber. It is not usually remembered that this surface acts detrimentally in two ways—firstly, during the power stroke, as explained by Mr. Scott; and also during the induction stroke, heat

A reader (Mr. C. H. Darby) just returned [illegible], enjoying the beauties of an English winter scene.

being then given to the gas at the time when it is of the greatest importance to keep it as cool as possible.

Of course, it is impossible to make an accurate quantitative calculation of the transfers of heat backward and forward between the cylinder walls and the working fluid, but my own impression, derived from practical experience, is that most of the loss of power caused by overheating is due to the heating of the charge during the induction stroke, as undoubtedly the power begins to fall off before the cylinder is hot enough to cause pre-ignition.

I am quite convinced that all air-cooled engines run with the combustion chamber much too hot for the best results, and that therefore a water-cooled head is a thing greatly to be desired in motor cycle engines, provided it gives no trouble.

From the above I am led to the conclusion that the overhead valve engine should be more efficient than the valve chest type. However, the latter is so greatly superior in reliability and general convenience that it quite rightly is in a great majority to-day.

C. A. ST. GEORGE MOORE.

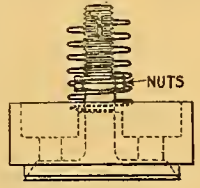
Ease of Starting.

[4543.]—With reference to Mr. H. Allen's letter [No. 20], in the last issue, may we draw this gentleman's attention to the Motosacoche, which is started in the way he wishes, i.e., by pedalling as a push cycle. It may interest this gentleman to know that the undersigned has never yet run alongside a Motosacoche and jumped on, as he does not know how to perform this trick.

MOTOSACOCHE, LTD.,
O. L. DE LISSA.

An Inlet Valve Tip.

[4544.]—I have a tip which may be useful to some readers who are troubled with constant breaking of automatic inlet valve cotters. I have found it to be a great advantage to have the stem of the inlet valve screwed with a fine thread, and fit two nuts locked together to give the correct distance for the valve to open. The old cotter pin hole is used for the threading through end of spring.



Readers will find that the nuts take up all the jar of the valve opening, and save cotters breaking. A. J. K.

Lightweights v. Heavyweights.

[4545.]—I notice in the issue of the 10th inst. that Mr. de Lissa has replied to Mr. W. L. T. Rhys's letter in answer to mine of a previous date. I did not trouble to reply to the latter correspondent, as I was quite convinced that he misunderstood the drift of my argument.

Naturally, I did not mean to convey that a 1¼ h.p. could travel faster than a 3½ h.p., or even as fast, but I still maintain that my 1¼ h.p. Motosacoche will climb Main Porth Hill—a gradient of 1 in 7 in one place a quarter of a mile in length, and which lies between my house and Falmouth—by the aid of some pedalling, which no 3½ h.p. machine has yet got up without very severe muscular effort on the part of the rider.

The reason, to my mind, is obvious. My Motosacoche weighs under 90 lbs., and the exertion of pedalling it, even on a very severe gradient, is not very great; while with a heavy 3½ h.p., weighing 175 lbs., and possibly more, in order to get round the corner, halfway up one must slow down, and then it is necessary to commence to pedal. The machine probably will not pick up at once; hence with the extra weight the muscular effort is necessarily very severe. If the machine does get to the top the rider must be an exceptionally powerful man.

No motor cyclist except myself uses this road, to my knowledge, on account of the severe gradients, and the fact that there is an alternative, though longer, route. I have tried this hill on two separate 3½ h.p. machines, and have never succeeded in getting to the top on either. With my Motosacoche I habitually use this road.

G. E. CASE-MORRIS.

Water Cooling on Motor Bicycle Engines.

[4546.]—Referring to the articles by "Ailette" and "Rotator," it may be interesting to readers to hear that I have been regularly using one of "Green's" patent water-jacketed engines, to which reference was made by "Ailette," for the past three years with unvarying success. The bore and stroke are 80 × 80 mm.

Whatever the final verdict may be as to the merits of water-cooling in comparison with air-cooling for engines of smaller sizes, there can be no question in my mind as to the very great advantages of the former in all cases where power is desired. My engine ran sixteen months without removing the valves, and then I found them in such an excellent condition as not to require any attention whatever. I have only once had them out since to grind after three years' running, and they are still gas-tight, but I am thinking of renewing them soon owing to the cotter holes being a little worn. I am still using the original sparking plug.

Overheating is unknown, and generally I find the engine requires much less attention than I was obliged to bestow on my air-cooled machines. I have had four since I first took up motor cycling in 1902. It is most economical in oil and fuel consumption, whilst the power is maintained under all conditions of load in a manner impossible in any air-cooled machine.

I have only quite recently removed the cylinder for the first time, after having run about 12,000 miles, when I found it, and the piston, very clean indeed, considering the distance run, and no appreciable wear.

Contrary to what many may suppose, I am never troubled with the water boiling, although I frequently take long spins in very hilly country with a sidecar attachment containing my wife and child, and the way the machine gets along with its load is an eye-opener to all those who see it. The water carried is about three pints, which needs replenishing at long intervals only, sometimes of several weeks.

Excepting for the three pints of water my machine is very little heavier than an ordinary one. HO 2.

SUMMARY OF CORRESPONDENCE.

Mr. A. C. Davison, 12a, Pleasant Row, Camden Town, N.W., is anxious to communicate with Mr. Joseph Adams, who wrote from Staffordshire, but who has apparently given his address incorrectly, as the reply sent to him has been returned marked "Not known."

Reverting to "Ixion's" comments in the last issue in regard to silencers in the T.T. Race, W. H. Wells writes: "'Ixion' suggests that it would be a good idea to make each entrant in the T.T. Race send in the silencer he proposed to use a month before the race, so that they could be tested and faked to make them uniform. 'Ixion' also suggests: 'It would be interesting if some fully qualified technical expert would take a standard silencer off some well-known machine, and see what percentage of efficiency he could obtain by removing its entrails and drilling out its end plates.' I wonder if 'Ixion' knows that the silencer as fitted to the Indian motor cycle consists of simply a round sheet iron box with pressed steel ends. In one end the pipes from the engine enter; at the other end a long pipe, extending out past the rear wheel, projects. This device is acknowledged by everyone who witnessed the reliability trials or the T.T. race last year to be exceedingly silent, yet evidently there is no back pressure. The whole secrecy of its efficiency in every way lies in the fact that there is a large chamber for the gases to expand in, and then a long pipe to carry the wasted forces out into the open air. I would, for the good of the cause in general, be pleased to see other makers of motor cycles copy this most efficient and simple form of silencing a motor cycle engine."

EXPERIENCES WANTED.

QUERISTS MUST SEND STAMPS FOR FORWARDING REPLIES TO QUERIES UNDER THIS HEADING.

"F. W. M." (Gillingham) desires readers' experiences with lightweight motor bicycles, especially as to reliability, comfort in riding, hill-climbing with a fourteen-stone rider, cost and frequency of repairs, and use in traffic.

D. S. Rothbury would like readers' experiences of the following 1910 models: Enfield, Hobart Bird, F.N. (2¼ h.p. gear-driven), and Moto-Rêve (2 h.p. chain-driven), particularly with regard to silence, flexibility, hill-climbing, and ease of mounting and starting.

CATALOGUES RECEIVED.

N.F. high tension magnetos are listed in a *brochure* to hand from S. Wolf and Co., 138, Southwark Street, Blackfriars Bridge, S.E. All types of magnetos are sold suitable for the various patterns of engines in use. The main features are simplicity and light weight.

Ariel motor bicycles are fully described and illustrated in a useful catalogue just issued by Components, Ltd., Bournbrook, Birmingham. Prospective purchasers should apply for a copy, as apart from the lucid descriptions of the Ariel motor bicycles and their appurtenances, space is devoted to many useful wrinkles.

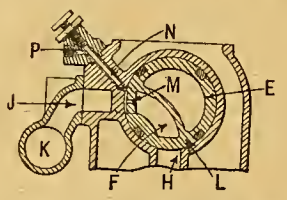
The 1910 Triumph motor cycle booklet is splendidly got up, and is profusely illustrated. First the bicycle and its component parts are described in detail and the advantages explained, and towards the end of the book many illustrations from the pages of *The Motor Cycle* depict the triumphant Triumph in last year's competitions. Four pages of hints on the care and management of motor cycles should prove most useful to novices. Copies of the booklet can be obtained on application to the Triumph Cycle Co., Ltd., Coventry.

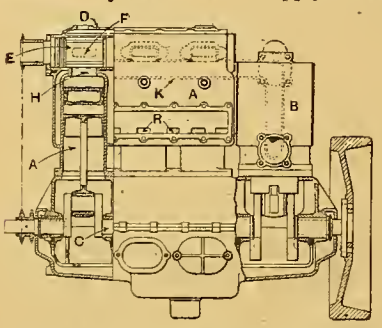
RECENT PATENTS.

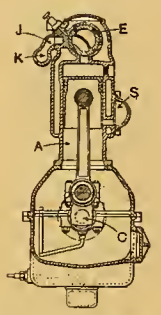
By ERIC W. WALFORD, F.C.I.P.A.

A Two-stroke Rotary Valve Engine.

The construction illustrated has three working cylinders A A A, and a pump cylinder B, all the pistons being connected to one crankshaft C. At the upper end of the working cylinders A is formed a casing D, in which rotates a valve E, driven by chain gearing at the same rate of revolution as the crankshaft C. The rotary valve E is provided with a port F for each cylinder, which, at the right time and for the correct period, puts the port H in the cylinder head into communication with a port J leading to the induction pipe K, to which air is supplied by the pump B. The port F has bridge pieces L, and in one of these is formed a slot M, the function of which is to take up a supply of fuel sufficient for one charge from the adjustable needle supply valve N, the inlet to which



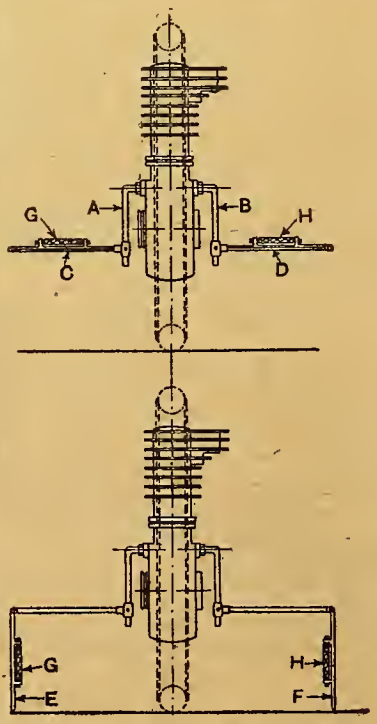




is shown at P. Each cylinder is provided with a number of exhaust ports R leading to a common exhaust passage S. In operation, as the crankshaft rotates, the rotary valve is rotated to bring the respective ports into register, the fuel being automatically taken up by the slot M in the bridge L as described. The pump B meanwhile supplies pure air through the inlet pipe, which in passing through the ports mixes with the fuel and forms the combustible charge. At the end of the down stroke the exhaust ports R are exposed, and the exhaust gas passes therethrough, being assisted by the fresh charge, which is timed to efficiently scavenge the cylinder, but not itself to pass into the exhaust passage.—A. G. Power, No. 26,729, 1908.

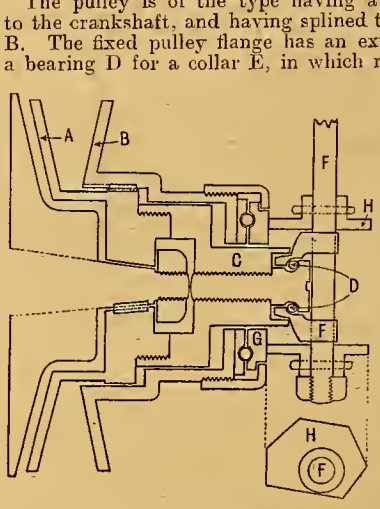
Combined Footrests and Stand.

Carried by the machine is a bar with two downwardly projecting portions A B. To these portions A B are adjustably secured rods C D, to the ends of which are pivoted further rods E F carrying pedals G H, which, in the position shown in the first figure, form the footrests proper. When it is desired to use the device as a stand, either or both of the bars E F are turned into the position shown in the second figure.—R. Hilton, No. 8,097, 1909.



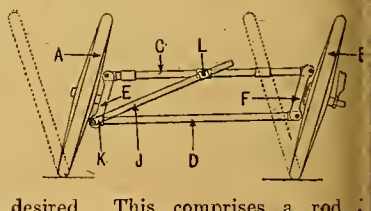
Variable Pulley Control.

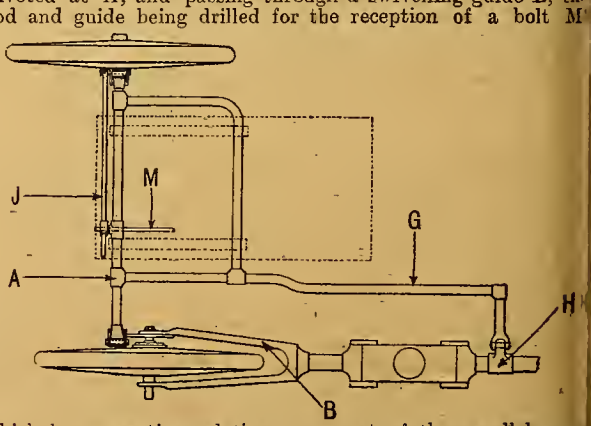
The pulley is of the type having a fixed flange A secured to the crankshaft, and having splined thereto a movable flange B. The fixed pulley flange has an extension C, which forms a bearing D for a collar E, in which rotates an operating rod F, under the control of the rider. The movable pulley flange B is provided with a thrust bearing G, against which acts a pair of cams H fixed to the operating rod F. The cams H in the case illustrated have six faces corresponding to a free engine and five different gear positions. No springs are necessary, as the tension of the belt moves the loose pulley flange outwards to the furthest extent permitted by the cams H.—A. Gnosill, No. 363, 1909.



A Flexible Sidecarriage.

The sidecarriage A is connected to the cycle B by mechanism which, operating on the principle of a "parallel ruler," always maintains the sidecarriage seat approximately horizontal. The mechanism comprises four tubes C, D, E, F, arranged in the form of a parallelogram, and jointed at their ends to permit of the necessary movement. A tube G extends forwards, and is secured to the cycle frame by a universal joint H. An arrangement is provided to enable the parallelogram to be locked rigid when desired. This comprises a rod J pivoted at K, and passing through a swivelling guide L, the rod and guide being drilled for the reception of a bolt M





which by preventing relative movement of the parallelogram maintains the rigidity of the sidecarriage.—I. Appleby, No. 931, 1909.

NOTICE.

The Editor disclaims all legal responsibility in any way for loss of copy in the form of manuscript, drawings, or photographs submitted to him. Rejected manuscript, drawings, and photographs will only be returned provided a stamped addressed envelope is enclosed for the purpose.

MOTOR BICYCLES FOR SALE.

ACCRINGTON.—Triumphs, 1910; Premiers, 1910; Zenith, 1910; Douglas, and Rex; we can give prompt delivery. Any make taken in exchange.

ACCRINGTON.—3½h.p. Minerva, spring forks, handle-bar control, Whittle belt, two-speed gear, and free engine, like new; £22 10s.

ACCRINGTON.—3½h.p. Vindec Special, spring forks, magneto ignition, in splendid condition; £17.

ACCRINGTON.—4h.p. Royal Riley, Fit-all two-speed, will suit tall rider, will climb a mountain; £13 10s.

ACCRINGTON.—3h.p. Quadrant, B. and B. carburetter, new belt, in splendid order; £7 10s.

ACCRINGTON.—3½h.p. Rex, surface, in splendid order, one of the olden times, but a trier, and successful; bargain, £6 10s.

ACCRINGTON.—3½h.p. Minerva, spring forks, magneto ignition, in good running order; £19 10s. All above are special bargains, and in working order.

ATHLETIC Supply Co., Accrington.

CROSS for Triumphs in Rotherham.—New 1910 and 1909 models in stock; second-hand 1908 Triumph £29; 1907 Triumph, magneto, £18; both in fine order.

2¾h.p. Minerva throughout, 1905, Dunlops, 26 by 2¼in., good running order; £8 10s.—Cross, Triumph agent, Rotherham.

LIGHTWEIGHT Douglas and F.N. motors, latest models in stock at 74, Bold St., Liverpool.—Hitchings, Ltd., are the sole agents, and invite enquiries.

SCOTT 2-stroke 2-speed Water-cooled Motor Cycles (for which Hitchings, Ltd., are the sole Liverpool and district agents), should be ordered now to ensure early delivery; send for descriptive catalogue.—Hitchings, Ltd., 74, Bold St., Liverpool.

LIVERPOOL Motorists should to protect their interests, buy Triumph, Douglas, Scott, and F.N. motors only from the responsible official agents, Hitchings, Ltd., 74, Bold St., who alone can substantiate the makers' guarantees, and also supply spare parts from stock.

TRIUMPHS.—Hitchings, Ltd. (the official agents), have several second-hand machines for sale at low prices, 1907, 1908, and 1909 models; all guaranteed; inspection invited.—Hitchings, Ltd., 74, Bold St., Liverpool.

BARGAIN.—3½-4h.p. 1909 Peugeot, perfect, new condition, modern, 1 w, stands, lamp, horn, spares, complete; cost 40 guineas, £25, or nearest.—80, Bispham Rd., Southport.

1909 P. and M., 3½h.p., excellent condition, winner of two gold medals, and special prize in A.C.U. 1,000 miles trials; £38 10s.—W. Milnes, Hallcroft, Wilmer Drive, Bradford.

TRIUMPHS, immediate delivery, come and see me before purchasing your 1910 mount, any make supplied; second-hand Triumphs taken in part payment.—Triumph Agent, 53, Trafford Rd., Salford.

READY for Delivery.—1910 Premier, 3½h.p., twin, quite the coming success, and undoubtedly the finest little jiggers on the market; 50 guineas; exchanges entertained; send for list.—Hardman, Stockton Heath.

1907 3½h.p. Magneto Triumph, h.b. control, adjustable pulley, F.R.S. lamp, generator, and horn, re-enamelled, plating excellent, machine and engine perfect, complete with spares; £22 10s.—No. 3,970, *The Motor Cycle* Offices, Coventry.

SECTION III.

Carnarvon, Denbigh, Flint, Cheshire, Derby, Stafford, Shropshire, Montgomery, and Merioneth.

3½h.p. Minerva, in good condition; must sell; £10.—F. C. Griffin, 30, Crompton Rd., Tipton.

3½h.p. Brown, magneto, spring forks, all accessories, not done 200 miles; £34.—Henshaw, wheelwright, Stockport.

TRIUMPH, new last January, splendid condition, rubber studded tyres, complete with all accessories; offers.—Benham, Holywell Terrace, Shrewsbury.

TRIUMPH, 1909, only run few hundred miles, guaranteed perfect order, non-skid tyres, complete with accessories; £38; only wants seeing.—Moss, Wem.

4h.p. Roc, magneto, two speeds, handle starting, take sidecar anywhere, practically new condition throughout; cost £56, sacrifice £27.—R. Else, Leawood, near Matlock.

1909 Triumph, enamel and plating as new, machine and engine guaranteed perfect throughout, searchlight lamp, horn, etc.; £37.—Browne, Beaconsfield, Oxton, Birkenhead.

SECTION IV.

Nottingham, Lincoln, Leicester, Rutland, Northamptonshire, and Warwickshire.

2¾h.p. Zedel, safe, low, and speedy, 26in. wheels, all spares; £7 10s.—Macer, 20, Park St., Peterborough.

1¾h.p. Minerva Lightweight, ready for road, condition perfect; £5.—Simpkin, 8, St. Margaret's Rd., Peterborough.

MOTOR BICYCLES FOR SALE.

TRIUMPH, 1909, free engine, overhauled at Christmas, £5 worth spares; £40.—3,941, *The Motor Cycle* Offices, Coventry.

4h.p. Twin, Peugeot engine, 21in. frame, 26in. wheels, fast and reliable; photo; bargain; 14 guineas. — Morris, photographer, Bourne.

TRIUMPH, late 1908, splendid condition, new Palmer cord tyres, spares; £32, no offers.—C. W. Blythe, 17, Market Place, Coventry.

F.N., 1909, 5-6h.p., in good all-round order; price £32, or nearest offer for prompt cash.—V. A. Holroyd, Warwick Av., Earlsdon, Coventry.

WOLF Lightweight, 1909 model, new rubber studded tyres, all accessories, perfect condition; £13.—Chatwin, 162, Hagley Rd., Birmingham.

MOTO-REVE, 1909, as new, only ridden 400 miles, guaranteed faultless and perfect; £25, with all accessories.—27, Smithford St., Coventry.

3½h.p. Bat, excellent condition, all accessories; must be sold immediately; owner going abroad; £10; offers.—D. Milner-Moore, Quadrant, Coventry.

3h.p. Ariel, spring forks, Palmer tyres, stand, acetylene lamp, etc., etc., perfect order, just been overhauled by Ariel Co.; £14, a bargain.—Fox, 136, Suffolk St., Birmingham.

3½h.p. 1909 Rex, excellent condition, just been overhauled by makers, new cylinder and valves, bearings rebushed, R.O.M. tyre back wheel, petrol and oil gauges, lamp horn, tools, all perfect; £34, or near offer.—Pooley, 187, Monks Rd., Lincoln.

IVAN B. HART DAVIES wishes to sell his End-to-end Triumph, 85 by 88 engine, two gallon tank, special handle-bars, spare butt-ended tube, all tools and spares, lamp, horn, etc., ran 2,000 miles, as good as new; £40 cash.—Apply, I. B. Hart-Davies, Bank St., Rugby.

3½h.p. Humber, two-speed and free engine, new last June, since overhauled by makers and fitted with 1910 improvements, including Druid spring forks, plain connecting rod bearing, new footboards and control, large belt pulleys, complete with lamp and tools, Dunlop tyres (unpunctured); £34, or nearest; bargain. — G.S., 37, Northumberland Rd., Coventry.

SECTION V.

Norfolk, Suffolk, Cambridge, Huntingdon, and Bedford.

3½h.p. Rex, two-speed, Roc clutch, magneto, as new; £30.—Leavis, Downham Market.

3½h.p. N.S.U., magneto, perfect order and condition, new tyres; £14, no offers.—3a, Bridge St., Cambridge.

3½h.p. M.M.C., Chater-Lea No. 6, copper torpedo tank, everything in good order; £9.—37, Searle St., Chesterton, Cambridge.

3½h.p. Rex, single-cyl., magneto, spring forks, Clincher tyres, long handle-bars, good condition; £12 cash.—Palmer, 39, London Rd., Ipswich.

SECTION VI.

Worcestershire, Herefordshire, Radnor, Brecknock, Monmouth, Glamorgan, Carmarthen, Cardigan, and Pembroke.

MOTOSACOCHE (accumulator), late 1908, spring forks, perfect; £17.—Dr. Burd, Upton-on-Severn.

1908 Twin Rex, excellent condition; too powerful present use; accept £27.—43, Pychin Crescent, Tredegar, Mon.

GLAMORGAN.—Brand new standard Triumph, 3½h.p. 1909 (late delivery), never been ridden; £42.—Newark Lewis, photographer, Port Talbot.

5h.p. Twin Sarolea, two-speed, free engine, chain drive, hand starting, in perfect order, and good condition; £20.—Jones, 104, William St., Ystrad Rhondda, Glam.

SECTION VII.

Gloucester, Oxford, Buckingham, Berks, Wilts, and Hants, and Channel Islands.

1909 Triumph, excellent condition, horn, spares, etc.; £38, bargain.—Morris, Holywell, Oxford.

2¾h.p. Kerry, low seat, long handle-bars, condition good; £11.—Lieut. Pinder, Victoria Barracks, Portsmouth.

2½-3h.p. Twin-cyl. Fairy Lightweight, excellent condition; £9.—J. S. Willway and Sons, Ltd., St. Augustine's, Bristol.

3½h.p. Quadrant, handle-bar control, carburetter, magneto, good condition and running order.—Morris, Holywell, Oxford.

N.S.U., 3½h.p., magneto, spring forks, condition as new, guaranteed; expert examination; £22 10s.—Claypoole, 63, Queen Sq., Bristol.

3¾h.p. 1909 N.S.U., magneto, handle-bar control, spring forks, practically new; £30.—J. S. Willway and Sons, Ltd., St. Augustine's, Bristol.

2¼h.p. Kerry Motor, complete, loop frame, new cyl., [illegible] spare cylinder, less tyres, accumulator, saddle; £4.—Motor, 11, Victoria Rd., Winchester.

As a chain is only as strong as its weakest link, a belt is only as efficient as its least considered essential.

The essential links in motor belting construction—Maximum effective pulling surface: Elimination of stretch; Tensile strength; Flexibility; Centring of core; Prevention of twisting, end breaking, and surface cracking—when evenly considered and supported by suitable materials and experience, ensure a perfect whole.

Camel Belting, owing to its uniform wear, due to scientific construction, is offered and sold as being the nearest possible to the ideal.

Obtainable through all Agents.

THE MOTOR CYCLE SUPPLEMENT

Motor Cycle and Cycle Show at Olympia.

At a meeting of the Show Committee of the Cycle and Motor Trades' Association, held on Wednesday last, the 26th inst., the offer of the Society of Motor Manufacturers and Traders to lease Olympia to the C. and M.T.A. for the purpose of holding a motor cycle and cycle show in November next was favourably received, and it was unanimously decided to proceed with the necessary arrangements. The decision of the C. and M.T.A. committee means that next November we may have three motor and cycle shows in London. It is probable that the car show will precede the Stanley, the date of which is November 11th to 19th, and the C. and M.T.A. Show will follow the Stanley.

In last week's supplement we referred to the "Association of Motor Cycle Manufacturers and Traders," but Mr. J. R. Nisbet reminds us no such association ever existed. What did happen was, at the last Stanley Show a proposal was mooted to form such an association, but it never got beyond the chrysalis stage, and, as we stated last week, the interested parties have now joined forces with the Cycle and Motor Trades' Association. Mr. Nisbet begs us to state that he hopes every motor cycle firm will immediately apply for membership of the Cycle and Motor Trades' Association, and so make that body strong as well as fully representative.

British Motor Cycle Racing Club.

The first A.G.M. was held at Carlton House, Regent Street, W., on Thursday last. Owing to the absence of Major F. Lindsay Lloyd (the president of the club), Col. H. C. L. Holden took the chair. After Mr. T. W. Loughborough, the newly-appointed hon. sec., had read an account of the doings of this active body, and the reports of three general meetings, the Chairman read the annual report, and then referred to the accounts, both of which were adopted. Mr. Loughborough was elected hon. sec., Mr. A. G. Reynolds hon. treas., and Mr. A. S. Ross hon. auditor. H.S.H. Prince Francis of Teck, K.C.V.O., D.S.O., is patron of the club, Mr. Locke King is vice-patron, and Col. Holden, R.A., F.R.S., president. The 1910 committee consists of Major Lindsay Lloyd (chairman), Messrs. Straight, Tessier, Hardy, and Pratt. It was unanimously agreed that a hearty vote of thanks be accorded to Mr. A. G. Reynolds for his past services in the interests of the club, and that the club sincerely regretted his ill-health, and that the wishes of the club for his speedy recovery be conveyed to him. One of the newly-designed B.M.C.R.C. medals is to be presented to Messrs. Reynolds and Ebblewhite as a small recognition of the splendid honorary work carried out by these energetic members, to whom the club owes its origin and success.

A.C.U. QUARTERLY RELIABILITY TRIALS. A quartette of competitors in Saturday's event. The machines are a Moto-Reve, Triumph, Wanderer, and Bradbury—all 1910 models. Inset, a competitor climbing Rectory Hill, Amersham, one of the test hills.

A.C.U. Quarter

THE Quarterly Trials of January, 1910, will be handed down to posterity as being famous for two reasons, firstly, the record number of entries (seventy-four were received), and secondly, because the weather and road conditions were of the worst. It had poured in torrents all the previous night, but at some early hour, when all good motor cyclists should be in bed, it froze and rendered the roads a sheet of ice. Of the splendid entry above referred to, the number of non-starters was exceedingly small, of these we may mention A. L. Onimaney (3½ Rex), F. J. Ellis (Matchless), who had an accident before the start, and F. W. Parnes (3½ Zenith), who was suffering from a chill.

A few minutes before the start a leakage from the petrol feed pipe of M. Geiger's V.S. caught fire, but was quickly extinguished.

At 9 a.m. on Saturday last, the following competitors were started from the Chequers Hotel, Uxbridge, by H. P. Beasley and W. H. Wells:

A string of competitors ascending Dashwood. The foremost rider is E. Kickham.

MOTOR BICYCLE AND TRICYCLE CLASS.

*Miss L. Berend (2 Moto-Reve)
*W. Cooper (3½ Bradbury)
*E. Leighton (3½ Triumph)
W. Pratt (3½ P. and M.)
W. W. Douglas (2¾ Douglas)
P. Phillips (2¾ Douglas)
G. Lee Evans (5 Indian)
*W. O. Bentley (5 Indian)
*J. S. Harwood (3½ P. and M.)
H. G. Bell (2¼ F.N. tricycle)
F. A. Applebee (3½ Rex)
*W. A. Lockwood (3½ P. & M.)
*B. A. Hill (2¾ Douglas)
*G. T. Gray (3½ N.S.U.)
T. Silver (3½ Quadrant)
A. T. Stanton (3½ Bradbury)
F. W. Applebee (5 Rex)
J. Gibson (5 Indian)
*E. Kickham (2¾ Douglas)
Eli Clark (2¾ Douglas)
F. A. McNab (3½ Trump)
J. H. Slaughter (3½ Ariel)
J. Holroyd (1½ Motosacoche)
*S. A. Whitham (3½ Triumph)
E. Stanley (3½ Premier)
B. Jones (3½ Premier)
F. Savory (3½ Premier)
F. Brown (3½ Excelsior)
R. Lord (3½ Excelsior)
*F. Thomas (6-7 G.O.K.)
*H. Bevir (3½ L.M.C.)
A. L.Barker (3½ Clyde)
*F. H. Stevenson (3½ Triumph)
*N. Kennedy (7-8 Bat)
C. J. Janssen (2 Moto-Reve)
*Howard Smith (3½ Triumph)
*G. L. Andrews (2½ Moto-Reve)
J. W. Leno (3½ P.M.C.)
S. C. Perryman (3½ James)
G. Allen (3½ James)
V. Underhill (3½ L.M.C.)
G. L. Fletcher (2¾ Douglas)
A. Oberlander (2½ N.S.U.)
*H. G. Partridge (3½ N.S.U.)
W. Ayling (3½ Midget Bicar)
*G. H. Lake (3½ P. and M.)
D. R. Clarke (3½ James)
W. Pershke (5 V.S.)
Eric S. Myers (3½ Scott)
F. Phillip, (3½ Scott. 2-stroke)
R. J. Bell (2 Moto-Reve)
J. Marshall (3½ Triumph)
W. F. Newsome (3½ Triumph)
C. T. Ringham (3½ Scott)
C. Dear (1½ Wanderer)
A. V. Deacock (3 Wanderer)
F. Smith (5-6 Clyno)
Howard Newey (3½ Norton)
*H. A. Cooper (2¾ Douglas)
J. V. Robinson (2¾ Douglas)
*C. Pattison (2 Moto-Reve)
*H. H. Bowen (5 Indian)
*P. M. Pridmore (3½ Triumph)

PASSENGER MACHINES.

*J. Tassell (8 Matchless)
M. Geiger (7 V.S. and sidecar)
A. G. Fenn (5 A.C. tricar)
H. C. Griffin (3½ Premier and sidecar)
*A. R. Abbott, jun. (8 Matchless and sidecar)
J. Portwine (5 A.C. tricar)
G. N. Higgs (5 A.C. tricar)
F. Eagles (6 N.S.U. and sidecar)

*Private owners.

At the start the weather was fine and the roads passably good, save where ruts and ice rendered them otherwise. However, at the foot of several of the hills the surface was most treacherous, and on Dashwood it was in an even worse state than it has ever been before on the occasion of a trial, as the road was practically covered with ice. As is usual on these occasions, the men were all stopped at the foot of the hill and restarted separately, their starting times being taken by A. V. Ebblewhite. Starting, however, on the ice-covered road was easier said than done. Many a man had a tumble, and one, so rumour had it, hurt himself rather badly. These frequent falls account for nearly all the failures on the hill. At the time of the hill test the weather was fine, but the summit was covered with a thin layer of frozen snow, while the cold and rather brisk wind was against the competitors. Considering the exceptionally adverse conditions, the men did marvellously well. As far as could be seen, the star performances were made by W. Pratt (who made a fine ascent, though impeded by another rider), Gibson, Evans, Bentley, Bowen, Marshall, Newsome, Myers, F. Phillip, and Kennedy. A. R. Abbott climbed Dashwood in excellent form, but most of the other passenger machines were troubled with the back wheel slipping. Miss Berend duly arrived at the foot of Dashwood, but was persuaded not to attempt the climb on account of the treacherous surface.

The following riders pedalled: Leighton, Douglas, P. Phillips, H. G. Bell, Hill, Gray, Andrews, Fletcher, R. J. Bell, Dear, H. A. Cooper, Robirson, and Pattison. It will be noticed that nearly all these are riders of lightweights. The following dismounted, nearly all through slipping: Stanton (fell, hurt elbow, and retired Aston Rowant), McNab, Slaughter, Holroyd, Janssen, Partridge, Ayling, Pershke, and Deacock. Eagles failed through the back wheel spinning round on the frozen surface.

iability Trials.

enced bad skids at Bletchingdon, and subsequently Pershke retired owing to magneto troubles.

The Hour Luncheon Stop.

The competitors commenced to arrive at the Red Lion, Banbury, at 12.20 p.m., and thereafter there was a practically continuous stream of riders entering the hotel yard, lunch being served immediately on their arrival. The checkers had a busy time dealing with such a large entry, and by the time the cards were all handed in, the first two or three competitors were ready for the return journey. The following riders lost marks through making adjustments to their machines in the control: C. Pattison (10m. repairing oil pump) and J. S. Harwood (15m. repairing puncture). T. Silver and F. A. McNab retired owing to falls on the outward journey. Fenn arrived very late, as also did Ringham and Dear, who reported having missed the route.

W. O. Bentley arrived at Banbury with the foot-rest of his machine badly bent, owing to a bad skid, but he told us he managed to keep in the saddle and prevent his machine from falling completely over.

The return journey was as usual, *viâ* Adderbury, Aynho, Bicester, Amersham (where the second hill test took place) and Uxbridge.

The surface of Rectory Hill was perfect compared with Dashwood, but hardly what might be called ideal, as several greasy patches had to be negotiated during the ascent. Wind blew up the hill, and there was a large crowd of spectators.

The following riders obtained full marks on Rectory Hill: Leighton, Pratt, Douglas, P. Phillips, Lee-Evans, Bentley, Harwood, Bell, Applebee, jun., Hill, Applebee, sen., Gibson, Whitham, Stanley, Joncs, Savory, Brown, Lord, Thomas, Kennedy, Janssen, Andrews, Fletcher, Phillips, Marshall, Newsome, Ringham, Deacock, F. Smith, H. A. Cooper, Robinson, Pattison, Bowen, Pridmore, and Abbott. Gray obtained eight marks, Bevir and Smith four marks, Dear two marks, Newey four marks, and Geiger five marks.

ashwood. Most of the fastest competitors had perforce to adopt the above tactics in hill-climbing to prevent a fall on the frozen road surface.

The Results.

The following is a record of performances of the various competitors:

R. Lord made a non-stop run; Thomas, non-stop, but took wrong turning; Bevir broke belt, and ran out of petrol; Barker dismounted Rectory and Chesham hills; Stevenson, side-slip, and failed Rectory Hill; Kennedy, non-stop, except three for traffic; Janssen, two stops, chain came off; H. Smith, failed Rectory Hill; Leno, side-slip, and failed Rectory Hill; Perryman, retired, broken valve gear; Allen, retired, broken exhaust cam; Underhill, belt troubles; Fletcher, non-stop; Oberlander, side-slip; Partridge, retired after side-slip; Ayling, one plug two traffic stops; D. R. Clarke, one stop Rectory Hill; F. Phillip, non-stop; Marshall, puncture, and forced on to a bed of stones by a car;

Preparing to leave Banbury after the luncheon interval.

Newsome, non-stop; Ringham, side-slip, and ran out of petrol; Deacock, fell at Dashwood; F. Smith, non-stop; Newey, dismounted Rectory Hill; H. A. Cooper, non-stop; Robinson, one side-slip; Pattison, traffic stop, and repaired oil pump; Bowen, two traffic stops, broken chain; Pridmore, non-stop; Geiger, reported non-stop; W. Cooper, thrown off at Dashwood by a rut, and failed on Rectory Hill; Leighton, punctured, and side-slipped; Pratt, side-slipped on Dashwood; Douglas, ran into a ditch, and broke belt; P. Phillips, traffic stop; Lee-Evans, three traffic stops; Bentley, traffic stop; Harwood, puncture, and dismounted owing to grease; Bell, two stops, wet on magneto; Applebee, jun., non-stop; Lockwood, retired, gear trouble; B. Hill, sooted plug; Gray, puncture; Gibson, traffic stop on Dashwood, and allowed second attempt; Kickham, side-slip, valve trouble, and failed on Rectory Hill; Clarke, stopped on Dashwood and Rectory hills; Slaughter, skidded on Dashwood, and failed on Rectory Hill; Holroyd, skidded on Dashwood, broke pedal, and failed on Rectory Hill; Whitham, non-stop; Stanley, two traffic stops; Joncs, non-stop; Savory, non-stop; Brown, non-stop; both the latter took wrong turning, and are said to have failed on Rectory Hill; Griffin, shortened belt, and tightened petrol union, failed on Rectory Hill through a slipping belt; Abbott, broke a belt fastener; Portwine, upset through a side-slip; Eagles, failed on Dashwood, belt trouble on Rectory Hill. At 7.25 p.m. all the starters had arrived at Uxbridge except McNab, Lake, Myers, Tassell, Fenn, and Higgs.

CLUB NEWS.

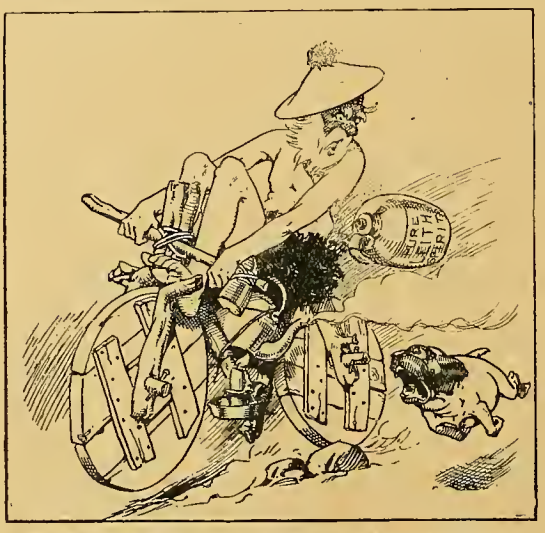
Edinburgh M.C.C.

The fourth annual dinner and presentation of prizes was held in the Carlton Hotel, Edinburgh. Members and their friends attended to the number of between fifty and sixty.

Mr. N. Macmillan, the president, was in the chair, and gave the toast of "The King," after which Mr. Bilbe proposed "The Edinburgh Motor Cycling Club," and congratulated the members on its well arranged competitions, and especially the way the Five Days' Trial had been carried out. Mr. McGregor replied.

Mr. Macallum then proposed "The Prizewinners" in a very interesting speech, which was replied to by Mr. Tolfree. "Other Clubs" was proposed by Mr. A. Allan Hay, the reply being given by Mr. Craig, of the Falkirk club. "Our Guests" was then proposed by Mr. E. L. Matthew, the captain of the club, and Mr. Geo. Hume, ex-president of the Scottish Amateur Athletic Association, replied thereto.

Songs and recitations were interspersed with the toasts, and those present spent a most enjoyable evening.



Design on front cover of menu card of the Edinburgh M.C.C. fourth annual dinner.

Bolton and District M.C.C.

The annual dinner will be held at headquarters, Pack Horse Hotel, on Wednesday next, February 2nd, tickets 3s. each. After the dinner Mr. A. E. Bennett will give a lantern lecture on "Magnetos," when it is hoped there will be a large attendance. Dinner, 6.30 p.m. Lantern lecture, 8 p.m.

Sutton Coldfield A.C.

Mr. Arthur E. Bennett lectured to the members on "Magnetos" on the 22nd inst. A good attendance was recorded, and the audience followed the lecturer with great interest from start to finish.

North-west London M.C.C.

The following fixtures have been arranged: Easter, inter-team trial to Harrogate and return with the Herts County M.C.C. May 7th, London-Coventry-London twelve hours run. June, inter-team trial with Herts County M.C.C. July 23rd, inter-team trial competition with the Oxford M.C.C.

Members are asked to communicate their intention of attending the club whist drive on Wednesday to Mr. Williams, 6, Kenmare Mansions, N.W., as soon as possible.

Herts County A.C. (M.C. Section).

A most varied and attractive programme has been arranged for 1910. The opening run is fixed for March 12th, after which the new clubroom will be opened and a smoking concert held.

The Service Co., High Holborn, London, have kindly offered a silver challenge cup or a shield, which is to be competed for in a long-distance inter-team trial.

Western District M.C.

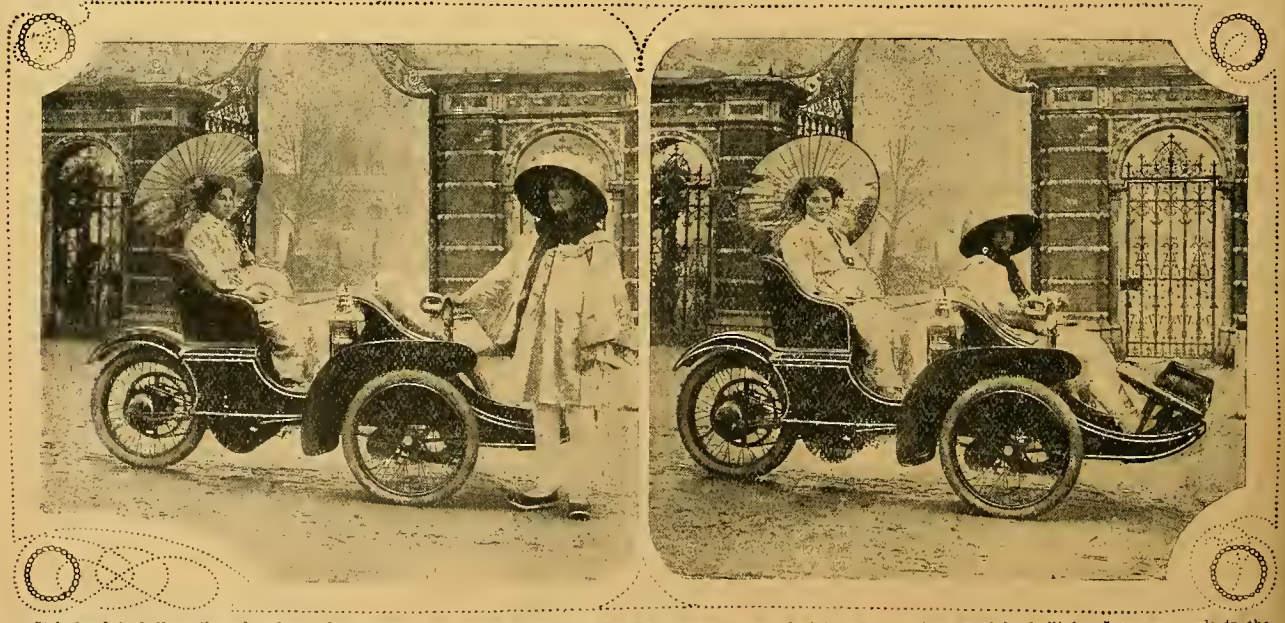
Mr. F. H. Mullett, who has devoted much of his spare time to the interests of the above club, has resigned the secretaryship. Mr. Mullett has worked untiringly to increase the membership of the club, and he has witnessed the membership grow from 38 in 1908 to the present total of 88. The new hon. sec. is Mr. I. J. G. Babbage.

Warrington and District M.C.C.

The annual general meeting for election of committee and officers, audit of accounts, will take place to-morrow at the Lion Hotel at 8 p.m.

Nottingham and District M.C.C.

Owing to the date of the whist drive clashing with the date of the General Election, the whist drive has been postponed until Friday next, February 4th.



It is hard to believe that the above photographs were taken in dirty, grimy old London. They depict an A.C. Tricar specially built for Japanese roads to the order of Mr. R. Sumi, Osaka, Japan. We had the pleasure of a visit from Mr. Sumi the other day, and next week shall have more to say regarding the tricar, and the riding conditions of Japan.

The Quarterly Trials.

PROBABLY not one single day of the whole year could have provided a more severe all-round test for a motor cycle than Saturday, January 29th, for the riding conditions were of the most trying description. A great many people imagined beforehand that the trial would be postponed, and it says much for the dogged pluck and skill of the competitors that so many non-stops were recorded. Again the results have demonstrated the usefulness of the trials, this time in connection with side-slipping and tyres. It is well known that steel studded covers are most efficient and thoroughly trustworthy in the most treacherous grease, but on ice-covered roads they were proved to be inadequate as anti-skids—in fact, accentuating side-slips. For all round work, that is, on ice-covered roads, muddy surfaces, and speed on dry roads, the palm must go to the all-rubber non-skid, many varieties of which were used with success in the trials referred to. We have closely analysed the results with the object of determining if any one type of motor bicycle stands out above the others when used under wintry conditions, but this does not seem to be the case. A good percentage of lightweights and heavyweights finished successfully, although we formed the opinion on the day of the trial that lightweight riders were having the most enjoyable time. Failures on the test hills were more numerous than one would wish, despite the fact that the competitors were once again stopped at the foot of each hill and the engines allowed to cool before tackling the ascent. However, it is difficult to draw comparisons, as the conditions admittedly have never been so bad. Finally, a word of praise is due to the promptitude of the A.C.U. judges, who issued the hill-climbing results the same evening, and the complete results in time for this issue.

The Buyers' Guide.

THE special feature of this issue is The Buyers' Guide, which consists of four pages of specifications of all motor cycles on the British market. The popular trend of design is noticeable from the Guide. For instance, the mechanically-operated inlet valve is very much more popular than the automatic type, and magneto ignition is so universally fitted to motor cycle engines that one could almost say that battery ignition is dead. Out of 169 machines, 161 are provided with magnetos, and only four have batteries. The ignition is optional on the remainder.

Belt drive is still the favourite form of transmission, and change-speed gears (denoted in the Guide by the word "variable" to distinguish them from adjustable pulleys) are gradually making headway. A large number of machines are fitted with adjustable pulleys, and probably by the time the 1911 Guide is issued they will be as universal as the magneto. The diameter of wheels varies so little that only eight machines diverge from the standard of 26in. diameter—two of these are ladies' machines and one a powerful tricar.

Nearly every machine has a spring front fork as standard, or it can be supplied to order. The few which have rigid forks are almost without exception either racing machines or lightweights.

Of twin-cylinder models the V type is an easy first. Passenger machines sold as complete vehicles are fewer in number than in previous years, which is to be accounted for by the popularity of the sidecar.

A Lady Motor Cyclist in Central Africa.

WE travelled in the same ship to the East Coast of Africa, but nobody, and myself least of all, could then have guessed how well acquainted we were destined to become. For it was a Triumph 3½ h.p. motor cycle, and I was a woman who previously had ridden nothing more spirited than a drop frame pedal bicycle.

We left the ocean steamer at the mouth of the Zambesi River, and, after a week's journey into the interior, arrived together in Nyassaland. Then our troubles began, but before relating them I must explain briefly why it was that I thus unexpectedly took to motor cycling in Central Africa.

Thirty Motor Cycles in Nyassaland.

There are, as far as I can remember, at least thirty motor bicycles in the country. This is a large number when you consider that the white population numbers only six hundred persons, and that the first macadamised road is only now being constructed. At present, however, except for one hundred miles of railway, motor bicycling is the only mode of quick travel available, and is most useful wherever there exists a fairly good earth path. It quite revolutionises the old ideas of distance by its extreme contrast to the other means of transport for which only human labour is at present available!

All this information I gathered soon after arriving in the country, and I was told, moreover, that besides being much less tedious than any other way of getting about, motor bicycling was also by far the least tiring—an important consideration in a tropical climate. I was strongly advised to learn to ride, and when I found that by this means I should, even when living in Zomba, the chief town, be enabled to get some big game shooting, my last doubt vanished, and I determined at all events to try.

Then it was, I repeat, that our trouble began, and we both suffered to some extent, though it was more often the Triumph that required doctoring than I did after our mutual encounters.

Early one brilliant morning, before the sun became too hot, I took a man's old pedal bicycle, and, choosing the croquet lawn, as being possibly softer to fall upon, I practised mounting from the pedal. There was not much difficulty about that, so the Triumph was next led out, its hissing breath filling me with awe. The various levers having been explained, I was instructed to push the ponderous thing along. Suddenly it came to life, almost leaping out of my hands, and I hurriedly lifted the exhaust lever.

"Why did you not get on? It is much lower than the pedal bicycle," said my teacher. "I will next time," I panted, and, in fact, I managed to do so.

For the next half hour I had a strenuous time, starting the bicycle and attempting to mount, usually with success. The sun was getting high, and I began to think this the most heating occupation it was possible to devise! Once more, and for the last time, I gave a vigorous push, the engine began firing, and I got my foot half on to the pedal. It slid off, however, and I lost my balance. The bicycle slipped out of my grip, and, as I fell to the ground, I saw it sail off by itself with a most determined air. It looked very fine I thought as it bowled along, but its owner, who wanted to catch it before it fell, was rushing after it, and for a few exciting moments it was anybody's race. In the end, the bicycle, eluding capture, swung round in a graceful curve, overbalanced, and fell heavily to the ground.

How I Enjoyed the First Ride.

The next morning the Triumph and I went out along the road. The start downhill presented no difficulty. Then for several miles I flew along before I could bring myself to stop, so delightful was it to be carried along by the powerful little motor. At last I pulled up, dismounted, and turned the machine round. Now for another attempt to run alongside and jump on! Running the bicycle along I tried to put my foot on the pedal quickly, but the attempt ended in failure, and we both fell down on to the hard dusty road. A bruised elbow and a bent foot-rest were the sum total of damages, but not disheartened, we were soon ready to try again. This time I resolved to be more cautious and to get someone to start me with a push. I called to the little group of natives, who had, of course, sprung up from nowhere, and were looking on with open-mouthed interest at my antics. In those days my knowledge of the native language was of the slightest. Still I managed to persuade one of the bashful creatures to come nearer and push behind the bicycle by taking hold of the luggage carrier. He trembled with fear lest the engine should go "bang." Sitting on the saddle I cried out "Koka!" and immediately the bicycle lurched backwards, I was nearly shot over the handle-bars, but just managed to keep

The writer, Miss M. Bridson on her borrowed mount.

A Lady Motor Cyclist in Central Africa.—

he machine upright. I was rapidly becoming annoyed t such stupidity when I suddenly remembered that had used the word for "pull" instead of that for push!" We began again; this time I said "Kanka," ll went well, and in a few seconds I was whizzing ily back to Zomba. When I arrived there my friend, ho had not expected me to be away so long, was ending out a machila to bring in he remains!

After this I had many a delightful ide, and seldom met with any serious ifficulties. On a good road mount- ng was easy, and where the path was ad or very narrow there was usually native willing to give the bicycle a ush, though he would often nearly pset it in his well meant efforts.

A motor bicycle nowadays creates omparatively little amazement mong the natives of Nyassaland. hey call it "Jinga," a corruption, believe, of the word engine. The boy" who looked after the riumph squatted near it all day, and kept it most xquisitely clean; the secret of its engine, however, was utterly beyond the power of his imagination to onceive.

How natives transport a motor bicycle in Ce tral Africa.

It was to me, too, very much of a mystery—in fact, rode in a state of blissful ignorance; and if anything ad occurred harder to put right than the breaking of sparking plug or the puncturing of a tyre, I should ust have had to drop the bicycle by the roadside and et home myself in some other way. This proceeding ould have been taken quite as a matter of course in Nyassaland, where no one ould or could have stolen he machine, and where a ew men would easily carry home for you, suspended rom a pole. Motor bi- ycling in Central Africa as, of course, special ifficulties of its own; but, xcept in the thorn tree dis- ricts, there is little fear of unctures in a country where either nails nor sharp tones are to be found on he roads. The roads are imply made of hoed and eaten earth. Now and hen, however, the surface s excellent, and a burst of peed may be enjoyed. But good stretch of road must ever lull your watchfulness o sleep. At any moment he spring forks may clash s you bump over an un- oticed rock just cropping hrough the earth; the road may suddenly narrow to a ath six inches wide; a tree may have fallen across he track; or the bridge at the bottom of a steep escent may have become a row of unconnected logs! The chief dangers, on the whole, are the patches of soft hick sand which occur in places. I went for a ride one day near Lake Nyassa, and the road frequently became nothing but a bed of dry yielding sand. It was extremely difficult to keep the front wheel straight and avoid a side-slip, for considerable strength of arm is required in such circumstances. But each time the bicycle got through all right, and I greatly enjoyed my long ride among the palm trees.

A machila (or hammock slung from a pole carried on men's shoulders) when encountered on the road is almost as difficult to negotiate as a stretch of sand. The two men carrying the front and rear ends of the pole would, when they heard the bicycle, invariably make for opposite sides of the road, causing the long machila to extend right across the path. Then, realising the situation simultaneously, they would quickly change sides, and so on *ad infinitum*, sometimes until you were forced to dismount before they arrived at a mutual understanding. On one occasion the men lost their heads even more completely, and, dropping the machila on the road, they vanished instantaneously into the bush. Choosing the lesser of two evils, I steered the motor bicycle over pole and hammock, but, fortunately for all concerned, there was nobody inside.

Nearly every one of my motor bicycling expeditions was enlivened by some unexpected incident. One day I met strange creatures on the road. First a mongoose dashed across, then I ran over a quickly wriggling snake, and here and there a thick black stream across the road showed that a migration of ants was taking place. On another occasion the machine and I seemed unable to remain upright for long together. I was riding out for a morning's shoot, for there is not much big game within fifteen miles of Zomba. The air was bitterly cold when I set out just before sunrise, and after a mile or two I was so numb that to warm myself I got off and ran briskly a short way alongside the bicycle. Then it was that when I was panting from the run and still stiff with cold I let the heavy machine overbalance, and drag me over on top of it. I succeeded in raising it up, and all went well for the next few miles. Then I tried to mount on a very narrow path with a deep ditch at one side. In a moment of aberration, caused I suppose by the effort of getting on, I forgot to steer. At any rate, I soon

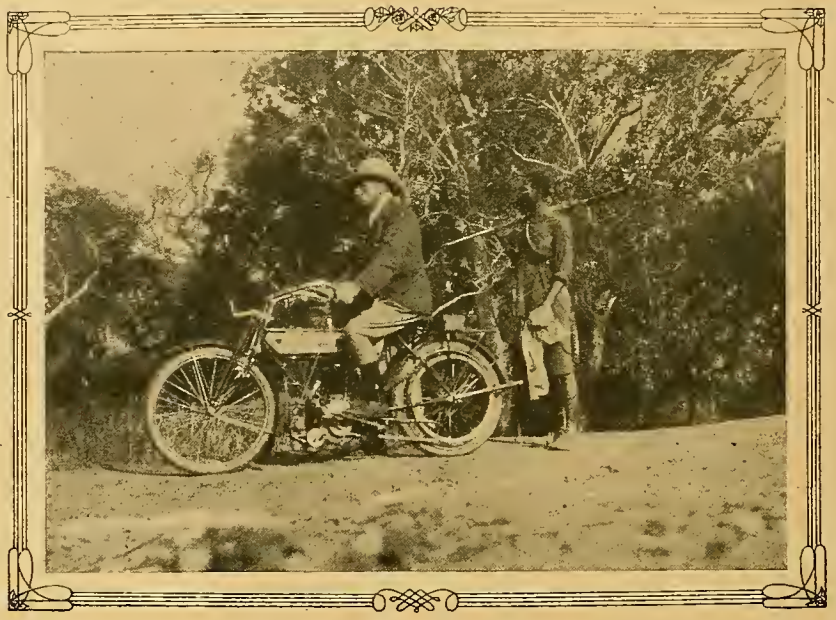
The only motor car in Nyassaland—an 8 h.p. Rover.

Found Myself in the Ditch.

The bicycle this time was "top dog," and its racing engine sounded very angry. A native who was near

A Lady Motor Cyclist in Central Africa.—

by and saw the incident came running up, groaning loudly with dismay. There was not much wrong, however, twisted handle-bars and a scraped shin being the extent of our injuries, and, remounting once more, we soon reached our destination. The chief disaster occurred three or four hours later when I was returning to Zomba. I rode rather fast round a hairpin corner, because there was a steep ascent immediately beyond the bend, and suddenly I found myself upon the ground. Even this time my usual luck was with me, and we were not prevented by a bent pedal and a cut and bruised knee from completing the run home to Zomba. But from this bout the bicycle recovered rather more quickly than I did.



After elephants on a motor cycle.

The last episode in which the Triumph and I were concerned took place many days' journey from Zomba, in the depth of the bush. We were on a big game shooting expedition, and were living in tents. The motor bicycle was with us, ridden when the path permitted not by me but by its lawful owner. On this occas we had been hunting elephants all day, and when got back to the village where we had left the bicyc in the early morning, we had been walking for ei hours without food, and had gone through sc exciting experiences. More than a little exhauste was not looking forward with pleasure to the six m ride back to ca on my ramshac old pedal bicyc But the mo came to the cue, and, lent me temporar carried me hc in spite of rough and nar path both ea and quickly.

Our part when finally I turned to Engl was, on one at least, a sad c for, in spite some mere temporary mis derstandings, had really got extremely together. A moreover, if lady living in tropical and pri tive country w in need of an easy means of travel, I could thoroug recommend the motor bicycle as an ideal mount, tho I think I should advise a lighter machine than which I rode in Nyassaland.

MARY BRIDSON

THE MOTOR CYCLE IN JAPAN.

IN last week's supplement we published two illustrations of an A.C. tricar specially built for use on Japanese roads, to the order of Mr. R. Sumi, Osaka, Japan. The design was altered to allow the coolie to steer and control the runabout from the front seat, while the rear seat for the passenger was raised and enlarged. This arrangement was to imitate as closely as possible the Japanese jin-ricksha, which is drawn and not pushed by the coolie. The narrowness of the roads in Osaka was the chief inducement to Mr. Sumi to select a tricar. When Mr. Sumi was in England he called at our offices, and discussing with him the utility of the motor cycle in Japan, he told us that there were comparatively few motor bicycles at present in use in the Far East. Probably the total number does not exceed 100, and they are mostly used in the neighbourhood of Tokio, and then only by rich people and the nobility of the country. Motor cycles are not cheap in Japan, as there is a fifty per cent. *ad valorem* duty imposed by the Government, which looks upon all forms of motor transport as more or less a luxury to be heavily taxed. The roads, and particularly those in the neighbourhood of Osaka, are narrow and unsuitable for motor traffic; in fact, Mr. Sumi told us that he considered the use of a motor bicycle in some parts of Japan would be dangerous.

MOTOR CYCLES AT THE MANCHESTER SH

ON Friday, the 18th inst., the annual exhibi of cycles, motor cycles, and cars opens at City Exhibition Hall, Liverpool Road, De gate, Manchester. This exhibition grows popularity every year, and there will be a represe tive display of motor cycles, including the un mentioned makes:

Northern Supply Co.'s exhibit (Stands 28, 29, 30).—Single and twin-cylinder Premiers (tou models), T.T. Premier, 4 h.p. and 6 h.p. N.S.U. sidecars, 1½ h.p. and 2½ h.p. N.S.U. bicycles, 5 Indians and a 7 h.p. Indian with two-speed gear free engine, Motosacoche, two-speed V.S. and side and Mills-Fulford sidecars.

Harold Thompson (Stand 111).—Four models the Wolf lightweight, including the 1¾ h.p., 2 h 2½ h.p. twin, and 3 h.p. twin.

Cookson Bros. (Stand 88).—Minerva motor bicyc

H. Reed and Co. (Stand 9).—Dot motor cycles.

L. F. Harvey and Co. (Stand 32).—A.C. tricar single and twin-cylinder Bat motor bicycles.

J. W. Gourlay (Stand 34).—Bradbury, Doug Ariel, Norton, and P.M.C.

J. G. Looker (Stand 7).—Moto-Rêve and Rex.

Velox Tyre and Rubber Co. (Stand 83).—L.M motor cycles.

THEORY v. FACT

It is a favourite but quite erroneous theory that because

"THE SILENT"

INDIAN

is capable of great speed it is essentially a speed machine. The error arises from a failure to appreciate the question of efficiency and power.

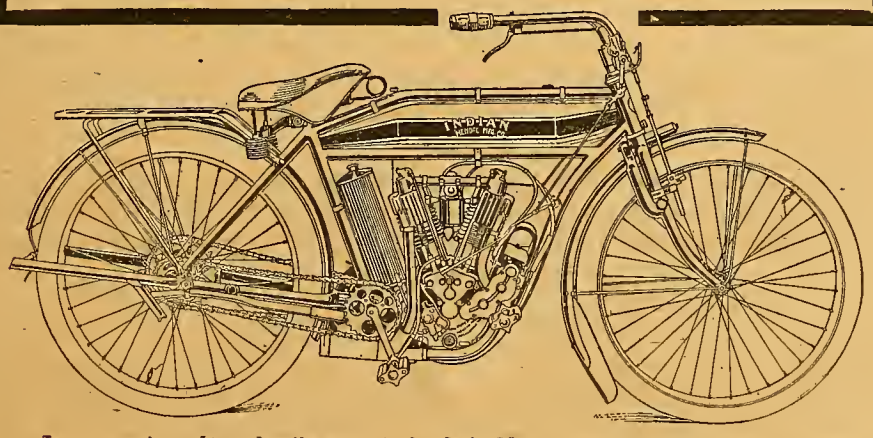
The most efficient machine is the one that gives the most power for its size, and speed is one of the results that may be obtained from power.

But it is not the only result. This extra power also means an ample reserve for hill-climbing, heavy roads, and for heavy riders. It is simply a matter of having the gear appropriate to the work.

The Indian motor cycle is noted everywhere for the tremendous power it develops for its size. Remember—

"INDIAN" means POWER

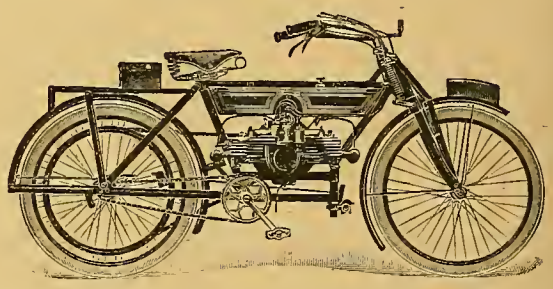
HENDEE MANUFACTURING CO.
184, GREAT PORTLAND STREET, W.
Telephone: Mayfair 1749. Telegrams: "Hendian, London."



The Douglas Lightweight

in the 1910 A.C.U. Quarterly Trials.

January 29th.



Reliability.

Mr. P. Phillips,
Mr. G. L. Fletcher,
Mr. H. A. Cooper.

All succeeded in making Non-stop Runs.

Out of an entry of 67, only 15 riders made Non-stop Runs. The Douglas Motor Cycles were the only lightweights to do this. This proves the exceptionally arduous nature of the Trials.

Hill Climbing.

Mr. W. W. Douglas,
Mr. P. Phillips,
Mr. B. A. Hill,
Mr. G. L. Fletcher,
Mr. H. A. Cooper,
Mr. J. V. Robinson.

Full Marks for Climbing Rectory and Dashwood Hills.

The Douglas succeeded where many heavyweights failed, and in spite of the treacherous condition of the roads.

In the 1909 Trials.

In the Trial in October last year Mr. W. W. Douglas made a Non-stop Run, gaining **100** marks (maximum possible), equalling the performance of any machine in the Trial; and Mr. B. A. Hill (private owner) made Non-stop, gaining 95 marks, only 5 marks less than best performance by trade riders on machines of much greater power.

These repeated successes under conditions much more strenuous than subjected to in ordinary riding or touring, prove beyond all doubt the reliability and efficiency of the Douglas Lightweight.

‡Two-stroke. * Private owners. † Luggage capacity.

NOTE.—The maximum number of marks obtainable are given in brackets at the head of the respective columns.

NOTES ON THE TRIAL.

The foregoing results have been especially arranged in the competitors' order of merit to enable readers to readily observe the close order of the running for the silver cup. Only two marks separate the first six competitors.

F. Eagles's failure to climb Dashwood was due to the steel studded tyre on the back wheel, and "not to the added weight of the sidecar," we are told.

One of the competitors distinguished himself by riding throughout the trial in a hard bowler hat.

G. N. Higgs, who drove one of the A.C. tricars in the Quarterly Trials, fell asleep whilst driving along, and was unlucky enough to have the tricar turn over on the top of him. When he came round again he found he was at the house of Mr. Brackley, Waterworks, New Ground, Tring, where he has received most kindly treatment. He had lost no marks up to Tring, and had only twenty-five miles more to cover.

Eric Myers lost his non-stop certificate through tempting fortune too far. For the Tourist Trophy Race last September he fitted ordinary Renold pedal cycle chains to his two-stroke Scott, and since then he has ridden the same machine over 2,000 miles. He made no alteration or replacement for the Quarterly Trials, with the result that at Berkhampstead one of the chains broke whilst he was climbing a hill.

Some of the competing machines were fully laden wit touring equipment, the 1910 L.M.C. was one of them.

Nine twin-cylinder and six single-cylinder motor cycl made non-stop runs.

The Scott Engineering Co. may be exceedingly proud their achievement in the Quarterly Trial. On the 29th ul the Scott two-stroke signalled its second appearance in quarterly trial by scoring highest marks.

Every lightweight motor cycle qualifying for a non-st award was shod with R.O.M. tyres. Of the entire numb of machines qualifying for non-stop certificates, 50% we fitted with R.O.M. tyres.

Besides being the first tricycle to complete the Uxbrid to Banbury and back course, the F.N. engine with i cylinder capacity of 250 c.c. was the third smallest finish, this in spite of its being handicapped by an ext wheel and a machine weighing as much as a 3½ h.p. bicycle.

We can only criticise the judges' awards in one respe Several of the competitors have been penalised for goi off the route (although it is admitted that in parts t marking was not what it might have been), whilst oth competitors who travelled off the course have been credit with non-stops.

CLUB NEWS

Middlesbrough and District M.C.C.

A most enjoyable and instructive paper is a most fitting comment on Mr. Alex. Lauriston's lecture, "The Law and its Relations to Motor Car and Cycle Owners." About fifty members were present, Mr. F. Scott presiding. The proceedings were brought to a close with a vote of thanks to the chairman and the lecturer.

Another Club for Leicester.

Regarding the leaderette in the last issue of *The Motor Cycle*, Mr. H. E. Smith advises us that it is hoped to form a motor cycle club for Leicestershire with the assistance of an exhibition to be held at Easter. Suggestions from local riders and proffered help would be gladly received by Mr. Smith, who is secretary of the Leicester Young Men's Christian Association.

Newcastle M.C.

The Newcastle Motor Club held another whist drive at the Royal Arcade Assembly Rooms, a large number of members and their friends being present. A most enjoyable evening was spent. The hon. sec., Mr. Alan G. Robson, reminded the members present that the annual general meeting is to be held at headquarters, County Hotel, on Wednesday next, 9th inst.

Harrogate and District M.C.C.

The annual whist drive and dance were held at the Imperial Cafe on the 28th ult. Despite the extremely bad weather some fifty members and friends were present and enjoyed the fare provided. On the 10th inst. a discussion will take place entitled "How to Physically Train for such Races as the T.T." On the 19th inst. a gymkhana has been arranged to be held at the Skating Rink.

Norwich and District M.C.C.

At the annual meeting of the above club, presided over by Mr. Everard, and supported by Messrs. Rackham, Poll, Pond, Pope, Smith, Chapman, Duge, Roberts, Bullen, Clem, etc., the following officers were elected: President, Mr. Bernard Thorne; vice-presidents, Capt. Duff, Mr. G. W. Bye, Mr. H. Chapman, and Mr. C. E. Rackham; hon. sec. and treasurer, Mr. Lincoln; committee, Messrs. Roberts, Bye, Peed, Lock, Smith, and Body; captain, Mr. A. A. Everard; sub-captain, Mr. H. Poll.

Oxford M.C.C.

The annual meeting took place on the 26th ult. Following the treasurer's and secretary's reports, the chairman, Mr. H. A. T. Packfe, in his remarks emphasised the importance of being affiliated to a governing body, instancing a case of a member who has received advice and financial assistance from the Auto Cycle Union and the Motor Union in connection with a fatal accident supposed to be caused by his motor cycle, resulting in a claim upon him for a substantial sum. Mr. Harvey Du Cros was elected president of the club with acclamation, and Lord Valentia, Alderman Salter, Dr. Collier, Dr. Jones, and Mr. H. A. T. Packford vice-presidents.

Mr. H. G. Hill, trials hon. sec., then submitted a full and interesting programme of competitions arranged for this year, reporting that he had received promises of substantial prizes, which will be published shortly. An attractive and successful year is anticipated, and new members will be warmly welcomed. Particulars of membership may be obtained from the hon. sec., W. A. Mathews, 6, St. Aldates, Oxford.

On the 22nd inst. the Rev. B. H. Davies will give a paper on "Aeroplanes," illustrated with 1in. models and lantern slides.

Walthamstow M.C.

The annual general meeting will be held at headquarters, Rose and Crown, Hoe Street, Walthamstow, on Wednesday next, 9th inst., at eight o'clock. It is hoped that the members will make a special effort to attend.

Manchester M.C.

The A.G.M. was held at headquarters, the Albion Hotel, Piccadilly, on the 28th ult., to receive the secretary's and treasurer's reports and balance sheet. The secretary's report was passed as extremely satisfactory, also the auditor's report. The balance sheet showed an annual turnover of over £350, and a loss of £55 on last year's working as expenditure over income. There is, however, a substantial working balance in hand. The election of officers and committee resulted as follows; President, J. H. Charlesworth; vice-presidents,

G. E. Stanley (3½ h.p. Premier), who was runner up for the silver cup in the 1909 Quarterly Trials, and has started 1910 well by making a non-stop run, and obtaining full marks on both the test hills.

P. A. G. Bell and J. Higginson, jun.; captain of car section, Percy Butler; sub-captain, E. J. Chambers; captain motor cycle section, H. Reed; sub-captain, C. E. Kettle; treasurer, F. C. Hunt; secretary, A. J. Moorhouse; committee, A. J. Bell, J. E. Tytler, J. H. Baynes, G. Ward, W. McNeil, J. T. Ward, T. Garner, E. Jones, and H. L. Cunliffe. A discussion took place on the competitions for 1910, and it was pointed out that every effort should be made to induce more entrants for the club competitions. Systems of handicapping prize winners were proposed, also competitions for novices. As showing the sportsmanlike feeling prevailing in the club ranks, subscriptions were then tendered in the room, first by the leading officials and then by ordinary members, in aid of the 1910 prize fund. One of £10 10s., followed by several of £5 5s., then £3 3s., £2 2s., and £1 1s. to the number of over twenty separate offers quickly brought the subscribed prize fund to about £70.

FURTHER NEWS FROM THE CLUBS APPEARS IN THE SUPPLEMENT.

BORE-STROKE RATIO & EFFICIENCY.

A. A. Scott's Reply to J. L. Norton's Criticism of his article.

MY thanks are due to Mr. Norton for his reply to my criticism of his article on the above subject, and also to Mr. C. A. St. George Moore for his letter in *The Motor Cycle* approving of my contentions.

I wish first of all to remind Mr. Norton that my criticism is primarily directed against his statement that "an increase of power is gained by an increase of stroke without any increase of capacity," and that, without being prejudiced in favour of either long or short-stroke ratios, I consider that so revolutionary a statement as this is entirely unjustified by our common engineering experience.

I have attempted to bring the advantages of both styles fairly before my readers, and if I appear to Mr. Norton to "turn the guns on my own ranks," etc., I take this as a tribute to the impartial nature of my investigation, so that, although in Mr. Norton's opinion "some of my arguments really serve to strengthen his case for the long-stroke engine," it still remains to be shown how and to what extent the long stroke is superior in power.

An Untenable Theory.

In my opinion Mr. Norton places himself at a considerable disadvantage in this discussion in having to make out a case for the long stroke in support of this quite untenable theory, and consequently we find that, while he deals at length in his article with all the points in favour of the long stroke, the corresponding advantages of the short stroke are ignored.

In reply to "especial pleading" of this sort, it was necessary first of all to find out the proportion of bore and stroke which constituted a long or short-stroke engine, and to select types that I considered more representative of motor cycle engines in use on the road, and then to discover exactly what happens in the cylinder of the engine, so as to be able to determine the value of Mr. Norton's trump card—the extra heating surface of the short stroke.

As pointed out by your correspondent, Mr. St. George Moore, "it is impossible to make an accurate quantitative calculation of the transfers of heat back and forward between the cylinder walls and the working fluid"; and since so much was made of this point, I attempted, by comparison with the overhead valve type, to find out to what extent this extra surface was responsible for loss of power.

This is, in Mr. Norton's opinion, waste of time, since I am told that it "has no bearing on the question at issue," and that I am "digressing here from the subject matter," while my brief reference to th valveless type is characterised as a "dissertation c the two-stroke engine, to which my article had r reference"!

In replying to the points raised by Mr. Norton, regret his remarks about my lack of sound argumen but am duly thankful for his admission that at lea some casual readers may be misled by my contributi to this discussion.

Now it is evident that Mr. Norton cannot get ov the idea that the short stroke must move faster to gi equal power, and all through his consideration of t subject, like "King Charles's head," he keeps brin ing in this quite unsupported theory, although in n investigation I have insisted upon an equal basis comparison, and have only referred to this capabili of higher speed as a separate advantage peculiar the short-stroke engine.

Consequently this is not, as Mr. Norton says, ov looked in my comparison of the frictional losses, that what he has to say here has no effect in dep ciating the "distinct gain in mechanical efficienc of the short-stroke engine.

Frictional Loss caused by Piston Rings.

I have certainly omitted to mention that b bearings can be applied to both types, because th is obvious and a necessary condition for a fair co parison, but I have insisted upon the fact that if well-proportioned bearing, and preferably a b bearing, is used in both cases, then, in spite of t heavier load on the bearings and on the side of t piston, the friction at these points "is quite negligil compared with the severe frictional loss caused by t piston rings."

This statement is in accord with the experience high speed steam engine makers, although apparen not admitted by Mr. Norton.

As for the increased diameter of piston ring in t short stroke, it is a well-known fact that the stren of the ring has to be increased out of proportion in t smaller diameter long-stroke piston, in order to p vide sufficient bearing surface on the sides of the r and to ensure sufficient local strength in the sect of the ring, so that the pressure of the large r against the walls of the cylinder would be for eq thicknesses actually less than that of the smal ring, although spread over a greater surface. fact, in very small cylinders below 2in. diameter it a difficult matter to make the ring with sufficient el ticity without reducing its thickness to an unsafe exte

e-stroke Ratio and Efficiency.—

In view of this, we can fairly allow in a practical rking engine more or less the same ring pressure in th cases, but we still find, when we have tied Mr. rton down to equal revolutions, that the long-stroke gine has to develop an extra amount of power to mpensate for a frictional resistance equivalent to nrly four strokes of the short-stroke engine.

Thermal and Frictional Losses Balanced.

Unfortunately, it is impossible to say definitely ether this frictional loss in the long-stroke engine exactly balanced by the thermal loss in the short-oke engine, since to arrive at this we would require take indicator and brake tests from both engines der equal conditions and at the same rate of revolu-n; but, failing reliable data of this sort, we can cite fairly assume that the thermal loss of the short oke makes up for the frictional loss of the long oke, and if Mr. Norton insists upon the short stroke ming at such a rate of revolutions that the thermal ses of each type are equal, then we shall probably d that the frictional losses of each are also equal.

Mr. Norton puts forth the original view that the ton speed is limited by "strength of materials" and wer of impulse, and contends that either type of gine can be run as fast; but since I have already own that the inertia of the reciprocating parts of t long-stroke engine is nearly twice that of the short oke, there would certainly require to be a very nsiderable additional strength of material, accom-nied with additional weight, if the revolutions of t long stroke were increased to the same extent as t short stroke, to say nothing of enormously increased g friction from its long stroke.

Referring to my figures on the subject of inertia d Mr. Norton's protest against what he considers a unfair shortening of the connecting rod to demon-ate the additional frictional losses in the long stroke gine. Evidently Mr. Norton has missed the whole point of my brief remark that "if, then, a rod only twice the stroke is used, the inertia of A (at top of stroke) = 707.7 lbs."

This has nothing whatever to do with increased friction, but since with the long-stroke engine a shorter rod is generally used, it was important to point out that this caused increased inertia at the top, although reducing the inertia at the other end of the stroke.

Immediately following this I pointed out that if a shorter rod is used, as is generally the case, "it is at the expense of further frictional loss."

Comparative Weight of Pistons.

Finally I am asked to explain how it is that a large diameter piston can be made lighter in proportion to its size. This is as explained in connection with piston rings due to the limit of local strength. For instance, a 4in. piston might have its walls $\frac{1}{16}$in. thick, while a 2in. piston would have to be made less than $\frac{1}{32}$in.—an impracticable thickness for a cast-iron piston. Then again the weight of piston should be in proportion to its area (since the load is in proportion to its area), and while the 2in. piston has 3.14 square inches, the 4in. piston has four times the area, or 12.566in., so that the weight per square inch is less in the large piston, even if we assume that this weighs twice as much as the small piston.

Regarding the weight of the longer connecting rod, this can be fairly assumed to be nearly double the weight of the shorter rod, for, although subjected to less load, the increased length calls for increased section to resist bending.

Finally, if Mr. Norton is correct in his assertion—"that by increase of stroke ratio we gain a definite increase of power"—then it follows that the greater the stroke ratio the greater the gain in power, and to show the absurdity of this statement, we have only to imagine the remarkable results which according to this theory should be derived from an engine $\frac{1}{8}$in. bore by 6ft. stroke!

TWO HUNDRED MILES OF MUD-PLUGGING IN A DAY.

"YOUR 1910 motor cycle is ready. Shall we forward same, or will you call?" Thus read a telegram addressed to me from the makers—Messrs. Bradbury and Co., Ltd., Oldham. "Forward same! Whatever was it made for!" I soliloquised. Why, certainly I will call at the works and ride it back.

And so it came about that January 1st found me at Oldham, and, later in the day, I took the machine for a preliminary canter, and made three clean ascents of Rippenden Bank (an exceptionally steep hill with a sharp bend at the stiffest portion), situated some fifteen miles from Oldham, over the moors. Every Bradbury, I am told, is tested on this hill, and has to climb it at a good speed before it is finally passed.

The following day I mounted my machine and bided for London. The condition of the roads from the outset was atrocious, and there was nothing to cheer me up but the steady pull of the well tuned engine. I never saw a dry bit of earth from the beginning to the end of the run. Greasy patches were in strong evidence, and looked anxious to make closer acquaintance with my clothes, but thanks to the R.O.M. non-skid tyres, the very low build of the machine, and the extremely smooth running engine, I soon acquired a feeling of comfort. As good as the 1909 Bradbury was, I like the 1910 model very much better. It is faster, and what is perhaps most remarkable, an even better hill-climber, for it must be admitted that the 1909 Bradbury is a hill climber of the highest rank.

Joining the Great North Road at Doncaster, I had no difficulty in attaining a most encouraging average in spite of the adverse riding conditions. The only real hill on the Great North Road from Doncaster to London is Gonerby Hill, near Grantham. The inches of mud which abounded precluded all possibility of rushing the gradient, and under these conditions most engines would get hot and knock; but not so the Bradbury. It simply took a deep breath when it found its front wheel above the level of the back one, and, gee whiz! like a rocket it shot to the top.

After a day's continual running the engine was so cool that I could keep my gloved hand on the cylinder. This, of course, means absence of valve troubles. During the whole run I was not caused a moment's anxiety, and I feel I have a motor bicycle of which I may be well proud. The Bradbury should assert itself in 1910 hill-climbs. B. B.

OCCASIONAL COMMENTS

BY "IXION"

A Spring Saddle Pillar.

Mr. W. W. Genn has just forwarded me a sample of his registered spring saddle pillar, which was illustrated on October 21st, 1908, page 815. In principle it is rather similar to the Druid fork. The saddle is mounted on an L-shaped piece of tubing slung from two clips by coiled springs, the clips being made to fit the frame tube of any motor bicycle. I have tried it on my rigid framed machine, and find it quite efficient in reducing road shocks.

Tank Filling Made Easy.

It is not every garage that owns a petrol funnel of motor cycle size, and in all big trials men are kept waiting till the funnel is available. I examined a machine this week which mocks at funnels. It is one of the new pattern filler caps, about two inches in diameter, with a permanent gauze filter fitted in the orifice. When the proud owner fills up he just takes a petrol can, loosens the cap, inverts the can with its snout in the tank orifice, slips the cap off, and lets the spirit run swiftly into the gauze well. Here is a device we could all do with, I fancy, saving time, temper, and trouble.

A Cute Suggestion.

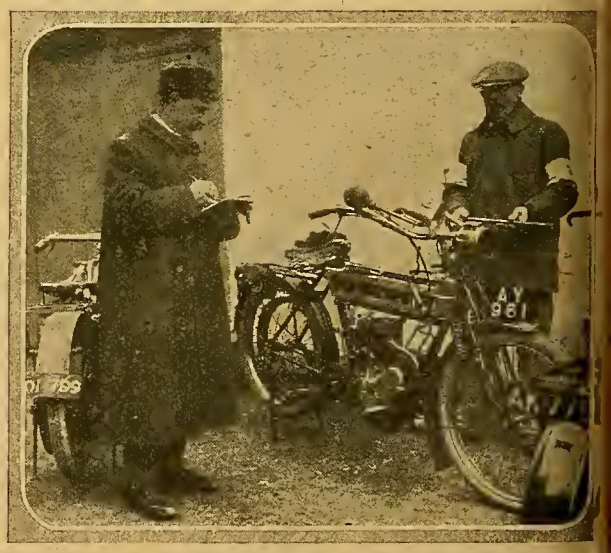
I was out last week on the car of an ex-motor cyclist, and I noticed that the extra air intake to his carburetter consisted of a long pipe brought up under his steering wheel, so that the air was sucked in from a district of the atmosphere which is always clear of dust. Judging by analyses of carbon deposit, this is just what we motor cyclists want. Both air intakes ought to be through pipes with their openings set near the saddle bow or the centre of the handle-bars; the one for extra air might easily be coupled up to the existing grip lever by a flexible wire. We should then get no grit in our cylinders, and the wear of our engines would be notably decelerated. Who will be the first daring innovator? I owe the idea to a correspondent of *The Motor Cycle*.

Exhaust Valves.

Not long ago I wrote one or two grumbles about the fragile construction of the modern exhaust valve. Granting that the two-piece valve with a cast-iron head screwed and shrunk on to a steel stem is a champion non-pitter, very few makers seem to have succeeded in perfecting the joint between head and stem, and valve breakages sometimes have serious results. Even if an intact valve head cannot jump through into the cylinder, the drilled heads often "fly"—*i.e.*, break into several fragments—and even if a segment does no damage, the cylinder probably has to be removed before it can be extricated. Many readers have written to confirm my experiences. I recommend some experiments in metallurgy. The contrast with the days of the old De Dion and M.M.C. engines is a lurid one—exhaust valves lasted us two or three years then; and granted that modern engines demand lighter valves of more slender construction, there must be metals and methods of manufacture which would give us a light valve as staunch as the old heavier types. One rider sends me an astonishing experience. I cannot challenge it, because I never owned a duplicate of his machine. He says that in 1906 he bought a certain first-class British machine and had to pay 15s. for a spare valve. He has ridden the machine constantly ever since, and is still using the original exhaust valve, which he has never once ground in. It is made of such excellent stuff that an occasional scrubbing with petrol has sufficed to keep it compression tight. In any case I regard the perfection of the exhaust valve as one of the most pressing problems which confront motor cycle engine designers of to-day. Personally I would rather use valves which pitted somewhat quickly than a valve which may break after 500 miles riding.

Tuning up for the Quarterly.

A few days before the last Quarterly Trial I was coming down Dashwood in a big hurry with the intention of reaching London before darkness set in, and I surprised seven riders tuning up their machines for

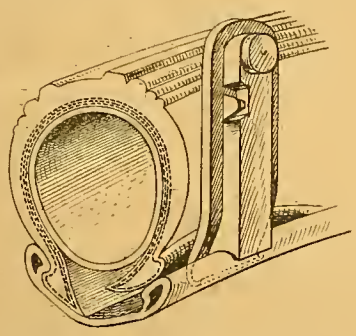


The A.C.U. secretary, Mr F. Straight, noting details of the new pattern Clyde motor bicycle ridden by Mr. A. L. Barker in the Quarterly Trials.

the event of the following Saturday! As no advantage is gained by scoring the fastest ascent, it is obvious that riders who took this precaution could not rely on climbing Dashwood at legal limit speed without a preliminary trial at the actual venue. One competitor had apparently brought out his machine on a car, and for all I know took it back to Uxbridge in the same inglorious way. This is a fine text for a dissertation on the private owner's need of variable gears. When trade cracks have nerves on the subject of Dashwood—a short, straight climb with no single figure gradient in it—it is evident that single-geared roadsters are not invariably equal to all possible demands.

BOBBETT'S TYRE GRIP.

Bobbett's self-holding tyre grips are fairly well known to autocarists, and the makers, Bobbett and Sons, 1 and 2, The Quay, Teignmouth, have now brought out a tyre grip for motor cycle tyres which we illustrate herewith. The illustration is almost self-explanatory, but for those who are unaccustomed to this device it may be advisable to point out that it is intended to supersede the first tyre lever used in replacing a cover on the rim, and which in the case of a stiff motor cycle cover (particularly if of the studded variety) has to be held by a second person, otherwise it slips and allows the cover to displace itself from the rim. With a Bobbett grip all that is necessary is to push the cover over, insert the grip, and fix it by turning down the pivoted lever until it is parallel with the hook portion, shown in engagement with the beaded edge of the rim. The grip is strongly made, nickel plated, and sold at a most reasonable price, and should be of great service to motor cyclists, particularly those who ride machines fitted with the heaviest type of covers, which are sometimes a little more than can be easily managed with one pair of hands.



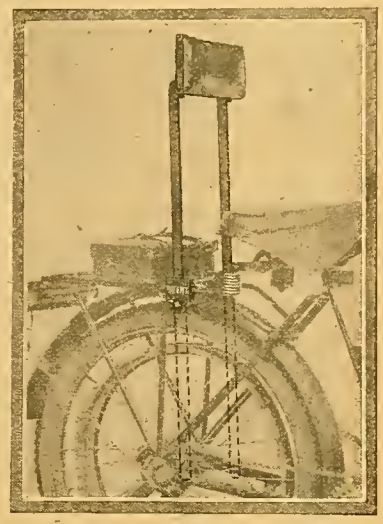
THE "IDEAL" SPRING FORK.

The latest type of spring fork to be placed on the market is the subject of the accompanying illustration, and is manufactured by Mr. F. J. Millard, Gilbert Road, Belvedere, Kent. It will be noticed that there are two complete forks, the front one to which the wheel is attached being the same as an ordinary rigid fork. The action of the springing is arranged on the lines of the parallel ruler. There are three pairs of links, the top pair being attached to the ball head clip of the steering column and the dummy steering tube of the spring fork, the centre pair to the fork crowns, and the bottom pair to the fork ends. Side play is therefore carefully guarded against, and it is claimed that the springs are so placed that immediately the shock is received it is absorbed by the springs, and is not transmitted through the fork blades. A front rim brake can be fitted, and the makers assure us that a sidecar does not affect the efficiency of the fork in the slightest. The forks are made to fit all makes of machines.

A new design spring fork known as "The Ideal."

ANOTHER BACK-REST FOR MOTOR CYCLISTS.

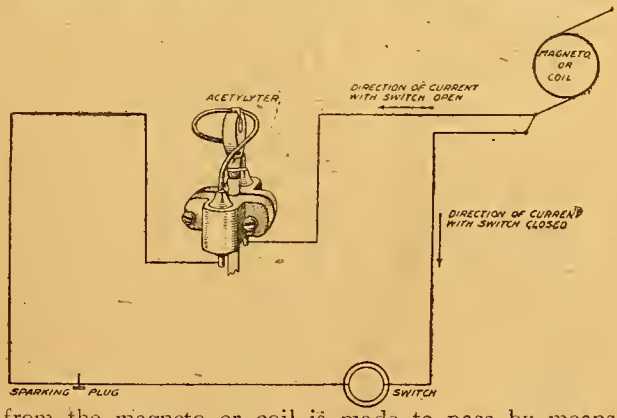
Particulars of another back-rest for motor cyclists have been sent us by J. W. Harrison and Co., 205, Corporation Street, Preston. Reference to the illustration shows that the two supports of the rest slide in guides attached to the luggage carrier. With the rest at its lowest position the rider mounts the saddle in the usual way, then by placing his hand behind he raises the rest to a convenient position. In case of a hurried dismount he merely leans forward, when the rest drops to its lowest position. It is claimed that it is impossible for the rider to catch his leg against the rest while dismounting. The rest is upholstered and fitted with a pneumatic cushion, which latter has a tendency to roll with the motion of the saddle, so preventing chafing of the rider's back.



Harrison's "disappearing" backrest which is designed to enable a hurried dismount.

A LAMP LIGHTING DEVICE.

Riders who wish to avoid the necessity of dismounting to light their acetylene gas lamps will be interested in an ingenious device called the "Acetylyter," made by Cox-Walkers, Ltd., electrical engineers, Darlington. The device illustrated in the centre of the wiring diagram fits over the lamp burner, and consists of an insulator carrying two wires, through which current from the magneto or coil is made to pass by means of a switch attached to the handle-bar. The diagram of connections shows the wiring suitable for magneto or coil. To light the lamp, the water in the generator is turned on, the switch opened, and the gas issuing from the burner is ignited by the spark. As soon as this occurs the switch should be closed. It will be noticed that fairly long high-tension wires are required to make the necessary connections.



THE MOTOR CYCLE BUYERS' GUIDE, 1910.

Specifications of all Motor Cycles on the British market.

Ever since 1906 the Buyers' Guide has been a much appreciated feature of "The Motor Cycle." For the purpose of reference it is invaluable to present and prospective motor cyclists, who are at this period busy weighing up the merits of each machine's specification prior to placing an order. The tabulated specifications enable comparisons to be made with a minimum of trouble, and in this connection we may remind readers that a straight edge or rule laid across the pages enables the line to be followed with ease. The particulars given hereunder have been furnished to us by the various manufacturers, a special form having been circulated by us for filling-in purposes. When, for instance, a certain make of machine is supplied with or without a two-speed gear, only one entry has been made in the Guide, "To order" being inserted in the Gear column to avoid needless repetition. In such cases the price given in the right hand column refers to the lowest-priced model. Whilst every effort has been made to avoid inaccuracies, we cannot be held responsible for any errors in the specifications or prices.

Water Cooling on Motor Bicycle Engines.

A REPLY BY "AILETTE."

I AM delighted to see that my short article on the above subject has created interest among both contributors and correspondents. "Rotator" has so nearly followed my own views, and has practically voiced them, so that I need do no more than refer to his article. Mr. Brooker's reference in his letter in the issue of the 17th ult. is in my opinion of considerable importance, as it emphasises a fact which appears to have escaped the notice of "Ixion," namely, that on the brave little Mototri-Contal water-cooling was the secret of success. He does not mention about its valves breaking, their pitting, or the rapid wear of the piston rings, but he says that the cooling on the thermo-spyhon system was the life and soul of the small engine. When first I penned the few lines advocating makers to experiment further in the direction under discussion I little thought such interest would be taken in the matter, and I must admit that I tackled the subject somewhat half-heartedly. Now, however, so much keenness has been displayed, and users of water-cooled motor cycle engines never before heard of are coming to the front and are voicing their experiences, I am glad I gave vent to my feelings, and am now encouraged to continue.

Air v. Water Cooling on Brooklands.

I should like very much to see machines with engines of equal cubical capacity water and air-cooled pitted against one another, say, in a twenty miles race all out on Brooklands, with the finish up the test hill. Under such conditions I feel sure that the water-cooled engine would win.

I am an old air-cooling enthusiast, and although I plead guilty to having been converted, I do not for a moment think that the air-cooled engine will be superseded for a very long time. I merely want to see the motor cycle compare more favourably with the car in reliability. Many will say it is equal, but it is not actually, as anyone who cares to compare the results of the Scottish A.C. car trials with the A.C.U. motor cycle trials will find out. Mechanical troubles, nearly always put down to bad oil, are more frequently encountered with motor cycle than with car engines.

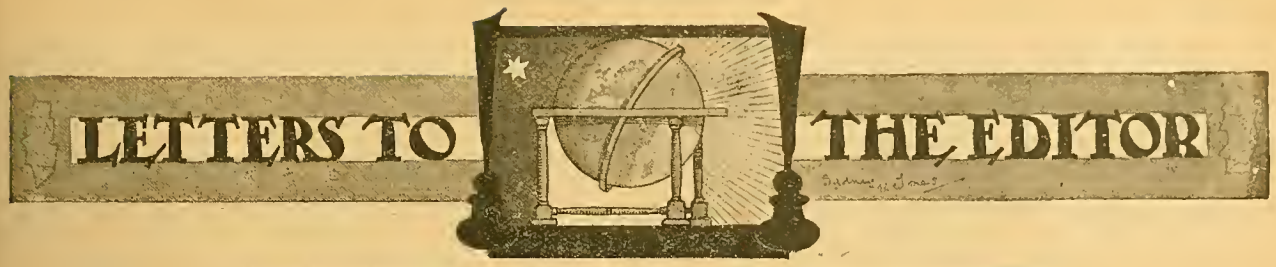
Referring to "Ixion's" criticism, I do not think it is in the least convincing. Granted that his M.M.C. and De Dion engines did not commit the seven faults enumerated in his observations, he does not say what would have happened had either been fitted with a water-cooled head. The addition would doubtless have added weight, but I feel quite sure he would have found that the machine with water-cooling would have been a far better stayer, even as was the miniature Mototri-Contal of which Mr. Brooker writes. Some years ago I took great delight in ascending Hindhead on an air-cooled tricar without changing down, simply by playing various tunes on my air spark and throttle levers. Such driving gives one the sense of conquering great difficulties, but water-cooling will do away with the necessity for all this, and though I regret it, I fear we must advance.

On a recent occasion I had an opportunity to cross the Little St. Bernard Pass on a car. On this great highway the road winds up apparently interminable zigzags to the sky, with a practically consistent gradient on the French side of 1 in 12, and about 1 in 8 on the Italian side. Would that such existed in England on the British Isles. Now on a climb like this a 2¾ h.p. water-cooled motor bicycle, geared about 5 to 1 or just a shade under, should, provided the rider exercised an ordinary amount of skill, make a comfortable job of the sixteen miles of ascent, but I very much doubt if an air-cooled machine would make a clean climb of it. What I want to prove is that, provided water-cooling is tried and made so as to endure what it will have to endure, we shall have a machine which will maintain its efficiency on long gradients, which will require less skill to drive it, and will keep in tune longer than the best modern motor bicycle. Surely it would be better to begin a series of experiments now than wait for the "better understanding of metallurgy" which will give us valves that do not break, to which "Ixion" vaguely refers. Classical readers may remember that Ixion's own mount which he garages in Tartarus is not cooled at all, but perpetually warmed by a nice fire.

Green's Water-jacketed Engine.

I am intensely interested by Mr. Catt's experiences with Green's water jacketed engine, and no one would be more pleased than I were Mr. Green to pay a little of the attention he is now giving to engines for aeroplanes which *may* fly to motor bicycle engines which will *undoubtedly* run. Mr. Catt's experiences are of real value, as they have been lengthy, but I fail to understand why he, who is presumably an amateur, should be so pleased with the arrangement, and yet firms in the Midlands, who had the chance of taking it up, did not do so. In making a water-cooled motor cycle engine the great point to be aimed at is to increase the weight as little as possible, and to do this it is necessary to study radiator efficiency very closely, so as to ensure the maximum amount of cooling surface, and thus be able to carry the minimum quantity of water. In conclusion, I want it to be distinctly understood that I do not expect the present type of air-cooled machine to be immediately superseded, but I want to see some enterprising firm produce a standard four-cycle water-cooled engine for motor cycles, and prove that what I have written is correct, or at any rate partly so.

The Continental Tyre and Rubber Co., Ltd., have now opened a branch depot at 63, Victoria Street, Bristol, to deal more promptly with their increasing business in South Wales and south-western counties.



The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, E.C., and should be accompanied by the writer's full name and address.

Road Dangers at Night.

[4547.]—I have noticed several times complaints of unlighted traffic on your roads. Most of the drivers of cattle, etc., out here, if they hear a motor, strike a match or two. Hint enough to slow down and look out for danger.

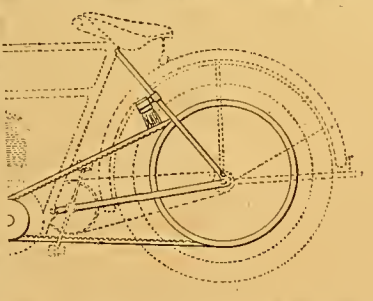
Parramatta, N.S.W., Australia. W. FLANDERS.

[4548.]—In view of some possible safeguard for night riders, may I add an experience of mine in this line. Coming home one dark night in a slight fog, going carefully, I first suddenly found myself in the middle of a flock of sheep, and wonder to this day how I managed to pull up and tumble off without serious accident. The men in charge were strolling along some twenty-five yards in the rear. A little further along I noticed that the fog appeared rather thicker ahead and so slowed up, and found that what my strong lamp had only made appear as thicker mist was in reality a huge load of straw in the middle of the road; no rear light, and the driver comfortably seated on the shafts ambling along as if the road was his personal property. Close in town I finished up my slow ride in a mixed crowd of sheep and cattle spread out on the road just as the first lot. The drovers, quite indifferent to my vociferous tootings seemed to treat my complaint (couched in fairly plain terms) as a good joke, and consigned me to nether regions. I certainly think that motor traffic should claim some regulation as to the carrying of green or distinctive lights by drovers and slow vehicles for their protection.

P. W. WALKER.

How to keep a Belt Dry and Clean.

[4549.]—It may interest your readers to know of a very simple arrangement I fitted to my Triumph to keep the belt always dry and clean. I have used it since last September in all weathers, and never had any belt slip. I purchased for 1s. a real bristle metal bound joiners' glue brush, and cut off the handle short. I then made an adjustable holder of 3in. × ⅜in. steel in the form of a figure 8, and fitted it on the back stay so as to allow the brush just to touch the belt as it leaves the pulley rim.



In practice I find the brush throws off any mud splashings quite clear, and as no mud or wet is carried past the brush my magneto is always clean.

It seems such a simple thing that I am surprised no one has tried it before; in dry weather it only requires pulling on one side. W. HEMSWORTH.

Racehorse v. Motor Cycle.

[4550.]—Having been for a number of years in one of the leading racing stables, and for the past eight years a motor cyclist, I was much interested to read the above query in your excellent paper; but I cannot endorse your remarks "That the motor bicycle should easily beat the racehorse." In the first place it would be impossible to obtain the "going" highly suitable to both competitors, and whereas a long and steady rain is necessary to make Epsom Downs good going for a racehorse, these conditions would be anything but *couleur de rose* for the motor cycle, and, on the other hand, should the Downs be hard and in their best condition for the motor cycle, the racehorse would be at a disadvantage, and would be very likely to break down if set to carry 13 stones over such a long distance. Probably the result would depend on the class and ability of the said racehorse, as you are well aware that there is as much difference between racehorses as, say, a 1902 1¼ h.p. Troubler and a six-cylinder Napier. However, taking the four-legged competitor to be an animal of equal merit with a Metropolitan Stakes winner, I will bet odds that the racehorse will win under any atmospheric conditions whatsoever.

Has Mr. Skertchley ever ridden a motor bicycle on a racecourse or similar pasture? I have, and I think he will find that fifteen to twenty miles per hour will be his best average, and he must not compare Epsom racecourse even with a fifth rate grass cycle track. I have ridden my motor cycle many times to Epsom Races, and have found that only on very short and clean patches of the turf is it possible to ride in anything like comfort at, say, ten to fifteen miles per hour. FATHERLESS.

[4551.]—In reply to Mr. L. E. Skertchley *re* motor cycle *v.* racehorse, if it is to be the Metropolitan course I should say the racehorse would be the winner. As you may know, it winds round like the figure 8, and, of course, you cannot go round at even thirty miles per hour. I may add I lived in Epsom for a good many years, and know every inch of the ground, and am also an enthusiastic motor cyclist. Provided the horse is a first-class one, my idea is it should win. I shall make an effort to see the race if possible, as I think it would be very interesting. W. MELLISH.

Club Life.

[4552.]—I read the leaderette in last week's issue *re* club life, also that your correspondent is a Northern clubman. As a member of the York County Motor Cycle Club, I can say that we should be only too pleased to have as many members of your correspondent's disposition as possible. I could not say that we are all between 40 and 50 years of age, but I can truthfully say that we have no "speed merchants." We certainly hold competitions, but rely on pleasurable touring for the success of the club. In fact, sociability was the main idea at its formation.

If your correspondent and other readers similarly disposed will apply to our secretary, W. E. Asquith, 11, Moreland Street, Leeds, I am sure he would be only too pleased to send them a fixture list as soon as we have it printed, and they will then see that we shall have a fairly busy touring season during 1910, provided we have fine weather. The principal tours (week-ends) for Easter and Whitsuntide have been arranged for Brooklands and the Lake District respectively. There is also a run fixed for every Saturday or Sunday during the summer, about 100 miles each, to some historical or otherwise interesting place.

With regard to the dust nuisance mentioned by your worthy self, our generally accepted rule is to ride in couples, keeping a fair distance behind anybody in front.

F. SCOTT.

Balancing Motor Cycle Engines.

[4553.]—With reference to an article which appeared some months ago on the balancing of engines, by "Winkie," it will no doubt be of interest to your readers to hear how the theory propounded by that gentleman works out in practice.

Fortified by a copy of the article in question, I conveyed my engine (a 1905 2¾ h.p. Zedel) to a local engineering firm,

the Colville Motor Works, High Road, Chiswick, for I would observe *en passant* that I found the straight-edge method for home balancing suggested by "Winkie" not nearly sensitive enough. The necessary weighing and drilling being accurately and cheaply performed by that firm, my engine was once more assembled and tried. The result certainly astonished me, for with a becoming modesty quite in keeping with the naïve simplicity of his *nom de plume*, "Winkie," only claimed an improvement in balance, whereas in practice I find that not only is this rendered perfect, but the maximum rate of revolution is enormously increased, as is also the power.

In subsequent conversation with Messrs. Colville, they informed me that the counter bob was 8½ ounces too light, and further surprised me by adding that in several engines which had recently passed through their hands for balancing on the above principle they had found them to be in some cases almost 2 lbs. out, but that in each case the correction enormously benefited the power as well as the balance.

In conclusion, I would strongly dissuade those who might care to profit by my experience from attempting to perform the operation at home, as, apart from the hopelessness of trying to test the balance without the aid of a fairly big lathe to swing the flywheels in, the time and energy involved in the removal of half a pound of metal with a hand drill are incredible, and not worth the trouble when the cost of having it done by an experienced motor engineer is so comparatively trifling. L. M.

Cost of taking a Motor Cycle to India.

[4554.]—I have just read with interest your reply to "Taking a Motor Cycle to India" in your issue of December 13th, and having only just received a cycle and a sidecar from the old country thought perhaps the enclosed would be of interest to you or some of your readers. I shall be obliged if you would let me know through the columns of your valuable paper the best book on the upkeep of a motor cycle.

THOMAS E. SAMSON.

Madras Presidency, India.

[With regard to Mr. Samson's query, he cannot do better than purchase "Motor Cycles and How to Manage Them" and "Hints and Tips for Motor Cyclists," each 1s. 2d. post free from *The Motor Cycle* Offices, 20, Tudor Street, London, E.C.—ED.]

Lightweights v. Heavyweights.

[4555.]—In reply to letter 4463, I doubt Mr. B. G. Durkin's statements. Might I ask what lightweights he really has ridden? From his remarks I think he must be somewhat more than young, active, etc., and knows little or nothing of lightweight motor cycles. A. D. TYLER.

[4556.]—I have been reading with much interest the discussion in your paper on the above, and was much amused at the letter from Dr. Gaskell in your issue of January 10th. I utterly disagree with him. My work requires everything he objects to in the heavyweight, and for which he praises the lightweight. My 3½ h.p. Triumph does everything that one can want, and therefore I maintain that it is merely a man's own requirements that make the real test. I start and stop as many as twenty or thirty times in a couple of miles, and my 3½ h.p. is (1.) Handy to get about on. (2.) Has every advantage he claims for a lightweight machine. (3.) It goes in and out of gates and doorways with no trouble, and is not the least trouble to "uphold." (4.) Has the extra advantage of absolute reliability when heavily laden, and never fails to start as promptly as any lightweight can be got to start, and does not give the belt trouble that a lightweight will give.

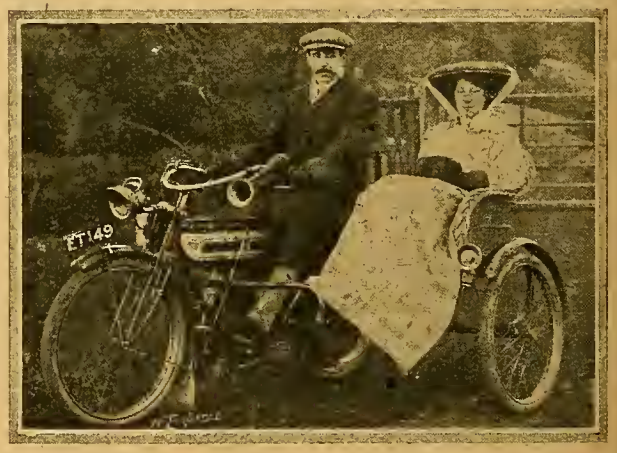
Now I maintain that just because I find the 3½ h.p. the best for the very kind of work he says the lightweight alone can do, and is the handiest for, it does not follow that in other hands the lightweight is not better, or that in my hands the lightweight would not give satisfaction. My experience of a lightweight has been one of trouble and annoyance, and barring the P. and M. I do not consider a lightweight has the least advantage over the 3½ h.p. (my experience, please; others have rightly other views perhaps), and so I say we ought not to say as he does that the lightweight is far better than the heavyweight. Anyway, after years of experience I find a 3½ h.p. of good reliable make has every advantage that a lightweight machine has, and the advantage of extra power and reliability and freedom from belt trouble that hardly any of the lightweights can yet show.

(REV.) R. MEASURES.

Experiences with a 3½ h.p. and Sidecar.

[4557.]—Many of your readers seem doubtful as to how a good 3½ h.p. performs with a sidecar and extra passenger, and I enclose photograph of my machine. I may say that my trusty Triumph has taken my wife and self many thousands of miles without any trouble whatever.

It may be interesting for you to know that I have no two-speed gear, but the ratio is as low as 6 to 1 with Whittle



The writer of the accompanying letter, Mr. G. W. Knapton, with his motor cycle and sidecar

belt. Many of your readers will know the hilly nature of Rotherham and district, and it is very rare I have to touch a pedal, even with a passenger. I may say that the combination comes in very handy for my business. I have to cover sixty miles every day in all weathers, and then I have to use it for cinematographing, etc.

Hoping this will be of interest, G. W. KNAPTON.

Antiquated yet Efficient.

[4558.]—I was very much interested in "Ixion's" remarks against water cooling for motor cycle engines in your issue of January 24th, and entirely agree with him that air is a better medium than water for the cooling of cycle engine cylinders, but with regard to the heavy weight of old pattern engines I cannot quite agree with him.

I should like to mention that I still ride a 1903 Ormonde motor cycle fitted with a 2¼ h.p. Antoine-Kelecom engine, which is light in weight, extremely efficient, flexible and fast, and is capable of hauling my 12 stones weight over Hindhead in Surrey at a good round twenty-five miles per hour without pedal assistance—this after having run on the road for six seasons.

I wonder if owners of 1910 models will be able to say the same of their mounts in the year 1916. R. BAMFORD.

The 1910 End-to-end Trials Route.

[4559.]—Referring to the proposed alteration of route for the 1910 Land's End to John-o'-Groat's Trial, I should like to suggest a slight alteration through the county of Somerset, which, if followed, would add considerably to the interest taken in the trials in this part of the country (Bristol). The route followed through the West of England is a singularly easy one, and is really no test for the modern motor cycle, there are a few short hills before reaching Exeter, but after there are no hills of any importance excepting Red Hill, which is really very easy to climb, as the gradient is not excessive.

I should suggest that when Cross is reached the route should be through Axbridge and the famous Cheddar Gorge, over the Mendips, down Harptree Hill (a fine test for brakes), through the villages of Chew Stoke and Chew Magna to Dundry, joining the main road just before arriving at Bristol.

This would include one of the best test hills in the West, and would give the competitors an opportunity of admiring the beauties of the Mendips. The road is quite good, and the surface of the hills excellent. It would add two miles only to the distance, making it a 1,000 miles run.

An idea of the route can be gathered from the contour book (Gall and Inglis), Western Division, Contour Section, No. 847, which is joined about three miles above the Cheddar Gorge at the Castle of Comfort Inn. A.E. 158.

Winter Riding.

[4560.]—In "Ixion's" "Occasional Comments" last week he comments on "the one dangerous surface," and I quite agree with him that it is impossible to keep up with ordinary tyres, as I found to my cost some weeks ago, when I had nine skids in a thirty mile ride.

The roads on the 31st ult. were exactly similar, yet by winding strong sash cord round the back wheel of my Triumph between every spoke, I have ridden with absolute safety and up several steep hills ice-covered and with the water running down them.

I am writing this in case it may be of use to any riders who may get stranded by going out in the early morning. The thaw coming on afterwards will soon make the roads into the condition described by "Ixion," and so render their return difficult or almost impossible.

I may say I rather fancy this sash cord tip may be useful to motor cyclists who have smooth or badly worn non-skid tyres, and who want to go out, but are afraid of skidding in bad weather. Of course, I have not tried the effect of ordinary roads on the cord, but intend to do so, as if it is successful it would be rather a good way of using up old non-skid tyres which have lost their properties through wear, but which may be otherwise perfectly good and sound.

P. WARBURTON.

The Motor Cycle in the United States.

[4561.]—The writer is very much interested to note in the issue of January 3rd the article by "Transatlantic"—"The Motor Cycle in the United States." The most interesting portion to his mind is the statement regarding the cause of the popularity of chain transmission.

The writer has ridden a machine since the second year the Hendee Co. commenced to manufacture the Indian, and started with chain transmission. Having read through the columns of *The Motor Cycle* of the advantages (?) of belt over chain I purchased last year, in spite of advices to the contrary, a 5 h.p. Indian, belt driven. In this season with a mileage of something over 4,000 I have used no less than nine different belts; three of these were the best rubber belts of English manufacture, and one a leather belt also of English manufacture; the balance were American leather belts with one exception, which was American canvas and rubber. The poorest mileage in every case was obtained with the English rubber belt, about 300 miles being the average life of same. They gave trouble by stretching and by cracking through from the canvas to the outside of the rubber, and I am given to understand that the makers state, in defence of their product, that the climate of this country is such that the belts will not last. On the last American belt used up to date the mileage has been about 800 miles, and the belt seems to be in fairly good condition at the present time. This would seem to refute the statement made by your correspondent regarding the shoddiness of the American product.

It might be directly in keeping at this point to say that the writer has sold his belt driven machine and is going back to the chain drive. The only advantage of the belt which the writer can see is the quietness, and this one advantage will certainly not offset the many disadvantages experienced, while with these improved chains now on the market this one point of superiority is being rapidly reduced.

Going through the various articles that have appeared in your columns, especially those regarding American records, the American motor cyclists appear to be classed with the direct descendants of Ananias, but be this as it may, one of your own authorities commenting on the Tourist Trophy Race, certainly gives the chain transmission a good word as compared with the belt drive.

In closing, the writer wishes to bring out the point that the supremacy of chain transmission in the United States is due to three things: Freedom of trouble, high efficiency, as proven in endurance runs and track meets, and minimum cost of maintenance, and not to the poorness of American belts as stated by "Transatlantic."

Mass., U.S.A. A DISGUSTED BELT USER.

[America must be a peculiar place! Fancy a "best rubber belt of English manufacture" which will not last more than 300 miles on a 5 h.p. twin—a day's ride—when similar belts on similar powered motor cycles in England usually last about 3,000 miles.—ED.]

Finish for All-weather Machines.

[4562.]—I am very pleased to note that of late in the correspondence and in your editorial remarks criticism has appeared and comment made regarding the excessive and unnecessary amount of plated surface on most motor cycles, which, unless carefully and frequently looked after, soon loses its finish and deteriorates.

In my own case I keep all bright work heavily vaselined; this treatment as applied to handle-bar, head springs, cranks, etc., is a comparatively easy matter, but the wheels that dredge up mud and wet, coating themselves at the same time, I decided required something more durable than vaseline. Accordingly, at the beginning of this winter I had spokes and hubs painted aluminium, which looks well, is easily washed and dried, thus saving much trouble; the rims being enamelled were not touched. Finding this satisfactory I specified, in placing my order for a 1910 motor cycle, that hubs, spokes, brake rods, and mudguard stays should be finished aluminium, rims black enamel; this the makers have most kindly agreed to do, thereby rendering me under an obligation to them for diverging from their standard practice.

I now hope in a few weeks' time to have a motor cycle that, if not noted or conspicuous for a Stanley Show brilliance, will be, better still, largely weather-proof, and capable of having dust and mud hosed off without a crop of rusty marks appearing afterwards.

This letter has been prompted, mainly in consequence of a question that appeared in *The Motor Cycle* of January 10th from "H.W.H.," who asked your opinion *re* a black enamelled finish on those parts usually plated, and if I may I would suggest that your correspondent should try an aluminium finish, which I certainly think he would find satisfactory and infinitely more pleasing to the eye than all black, which, judging by a new pedal bicycle I inspected recently, presents a very sombre and funereal appearance.

R. G. LINDSAY.

SUMMARY OF OTHER CORRESPONDENCE.

The Stevenson Patent Valve Spring Lifter Co. write: "In reply to letter 4519 in *The Motor Cycle* of the 24th ult., may we inform 'Plug' that we know that a valve spring lifter as suggested by 'Plug,' when the cotter is burred after a large mileage, would only result in the breaking of the radiating fins. A valve can be removed with our lifter in under thirty seconds."

EXPERIENCES WANTED.

"Tandem" would like readers' experiences with the Millennium two-speed gear for engine-shaft.

"H. E. R." would like readers' experiences of the Z.L. twin-cylinder engine, aslo the Nala two-speed gear.

"LC 7611" would like readers' experiences of the Wall Auto Wheel, particularly with regard to reliability, ease of starting, and control in traffic.

"Edgar" would like readers' experiences with a two-speed gear and free-engine or free engine alone fitted to a Douglas.

A selection of questions of general interest received from readers and our replies thereto. All queries should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, E.C., and whether intended for publication or not, **must be accompanied by a stamped addressed envelope for reply.**

Carbide.

Can you please tell me if there is any way to make carbide last longer? I charge my generator before going out of an evening, and it seems to last only about two hours, and on first lighting flares up in a most alarming manner.—K. W. S.

Obviously you turned on the water too much when you first set the lamp going. The water should be turned on very gently, or you may turn it on to the usual amount and then turn the tap back until the normal amount of gas is given off. You may also find coated carbide to be slightly more economical.

Studded Covers for Preventing Side-slip.

My 3½ h.p. motor bicycle is fitted with ordinary plain tyres, and skids badly in mud, especially when passing traffic on cambered roads; the front tyre will not grip. Shall I fit steel-studded covers or rubber-studded covers? Which is safer for touring?—P. C.

On very muddy roads a steel-studded cover is best for the rear wheel, but for town riding it is better to use a rubber-studded cover, or a combination rubber and steel-studded cover. In any case it would be advisable to have a rubber studded cover on the front tyre. As we infer, steel-studded tyres are the most efficient on muddy roads, but should the road surface be covered with ice or snow they are likely to cause trouble.

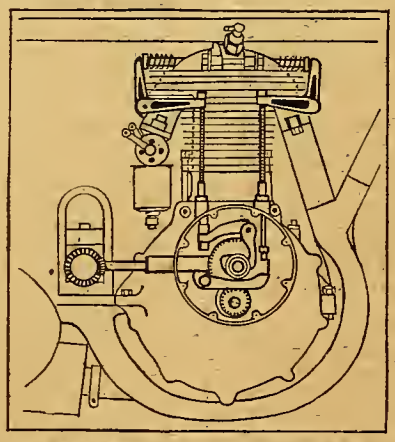
A Red-hot Cylinder.

My engine is a 3⅜ h.p. old pattern. At the end of a four or five miles run the metal portion of the sparking plug and the engine in the neighbourhood of the inlet valve becomes vividly red-hot. The gas is throttled right down and the engine will take full air. (I am certain that the mixture is not too rich.) Is there any danger, owing to the engine getting in this state? It sometimes fires when switch is "off." But the casting is quite smooth, and there is no carbon deposit. Also there is no electrical leakage.—H. J.

We imagine that you have a habit of driving with the spark lever too much retarded. This would quickly cause overheating. If you attend to this, and also lubricate more frequently, we feel sure you will not notice the same symptoms, provided, of course, that (1) the cylinder and piston are clear of carbon deposits, (2) the casting is smooth internally, (3) the exhaust valve lifts to its full extent, and is timed to commence opening when the piston is within one-tenth of the end of the firing stroke. The premature firing is probably due to the plug points becoming white-hot.

Using Too High a Gear.

Can you please suggest anything to improve the power of my 1907 3½ h.p. bicycle, magneto ignition, geared 4½ to 1, Longuemare carburetter, 9 jet and 21 choke tube, magneto timed correctly and sparks regularly, automatic inlet valve which opens ½in., exhaust valve opens ¼in? It is timed to close when piston reaches top of stroke and opens before it reaches bottom. I have cleaned piston and cylinder head, also ground in valves.



A motor cycle engine with horizontal valves in the cylinder head, operated by push rods and bell cranks. It is the Royal Pioneer, an American make. Observe the bevel drive for the magneto.

Compression will stand twelve stones on pedal for about half a minute. Machine runs very fast on the level (forty to forty-five miles an hour), and will take full air when going all out, but it will not climb short steep hills, nor a long gradual hill of about a mile long, and about 1 in 12 gradient. When slowing down on a hill the engine knocks, and I have to retard the spark. I do not think it is overheating.—J.K.

Your trouble seems to be entirely due to the high gear you are using. If you lower the ratio to 5 to 1 the machine will perform better on hills, but the speed on the level will be reduced. We should advise you first of all to try the effect of a lower gear.

Engine Knocking with Spark Retarded.

I notice a severe knocking in the engine, especially on hills, and no matter how I retard the spark it still continues, but if I partly raise the exhaust lifter the knocking stops. Some little time back I had to have a new connecting rod and piston, which when returned made the compression space just half what it was formerly. Probably this has caused the trouble. It is a 3 h.p. Singer, belt drive, and before the accident I never knew what it was to have a knock in the engine, and there was just about half the vibration.—C. R.

The knocking, we should say, is entirely due to the compression ratio having been increased. If you made no amends for the longer connecting rod, by placing packing between the cylinder and crank case, it would be advisable to fit a metal or fibre washer to raise the cylinder higher, and so lower the compression. Or you might return to a shorter rod. Other causes of the knocking when the spark is retarded are (1) too high a gear for the weight carried, (2) a loose bearing, and (3) excessive carbon deposits.

Local Taxation Exemptions.

Is it compulsory for me to pay a tax for my motor cycle, which I only use for business purposes, namely, carrying papers for the *Evening News*? I had the Revenue officials call on me three years ago, when I purchased a tricar, and they informed me that I should have to pay a tax for that as well, because at that time I was using the motor cycle for pleasure, but I have not ridden it for such since.—H. J.

We are afraid that you will have to pay the tax, as there seems to be no way of getting out of it at the present time. Of course, provided you have a carrier fixed to your machine, adapted for the carrying of your newspapers, and your name and address are painted on this in letters not less than 1in. in height, you should, according to the present state of the law, be exempt; but in the recent case of Moore *v.* Lewis it was pointed out that it was possible to use the motor vehicle in question for other than business purposes, and although the defendant assured the court that he had not used it for his own pleasure, the case was decided against him. The only hope seems to be to wait until there is some chance of amending the law.

The Control of the Spark Lever.

My experience so far has only been with a motor bicycle fitted with accumulator ignition. I have now ordered a Douglas with magneto. Shall I with magneto ignition follow the old rules, viz., retard for starting and open throttle wide, throttle down and advance spark for average speed and economy, open throttle and retard spark for long steep hills, open throttle and advance spark for rushing short steep hills? Also what oil should be used for lubricating magneto, and how often necessary?—H.R.

You will find magneto ignition to be a real improvement. The method of driving, however, must be slightly altered. The control of the spark lever depends entirely upon the timing of the magneto. For instance, most machines are timed in such a way that the lever is always left fully advanced whether for starting, slow running, or fast hill-climbing. Other makers time the magnetos so that they should be two-thirds advanced for starting and general running, and only retarded very slightly when it is desired to travel especially slowly. You alter the spark advance far less with a magneto than you do with accumulator ignition. With the magneto you set the spark fairly well forward (fully forward if you wish to travel fast) and drive entirely on the throttle, naturally adjusting the air to suit, and only retard when the engine knocks, and that slightly. For the magneto, you may use any medium grade oil, such as gas engine oil. With the modern ball bearing magneto very little oil is needed, a few drops every 200 or 300 miles will be sufficient.

Engine Stiffness. Knocking.

(1.) I have a late model 1909 two-speeder, and have a difficulty in starting, as the piston seems to gum up after standing overnight, and it is almost impossible to turn the starting handle. I have tried injecting paraffin, petrol, and a mixture of oil and petrol, but it takes a large quantity of any of them and much hard work with the starting handle to free the engine. Lubricating oil used is Price's air-cooled. The local agent has not so far been able to improve matters. When once the engine is warm the piston is quite free, and the machine easily started. Can you suggest a remedy? (2.) Another trouble is the tendency of the engine to knock at all speeds below 20 m.p.h., even with ignition well retarded. Hill-climbing is bad unless hill can be rushed. Thinking gear possibly too high I opened adjustable pulley as much as possible; this had no apparent effect except to make low speed very slow. Can it be due to wrong adjustment of carburetter or timing of ignition?—V.H.

(1.) The thickest air-cooled oil is not suitable during cold weather, as the engine so quickly gums up. Try the same brand B quality, or use half water-cooled oil and half air-cooled. Probably after you have used the engine a little longer it will not gum up in the same way. We can offer you no better advice other than to give it a copious dose of paraffin either before putting the machine away after a run or before starting. (2.) We should say that your engine is timed too fast if knocking occurs with the lever retarded, and especially as hills can only be rushed. If the engine will run slowly and you can make it misfire by opening the air lever fully when the throttle is about half open, the carburetter should be adjusted correctly.

Engine Not Responsive to the Throttle.

My Lagonda tricar runs well enough, but does not respond to opening the throttle on hills. I conclude that the carburetter (Longuemare H. or E.) needs adjustment. Would you kindly tell we what is probably the defect and remedy? Also would you tell me—(1.) The effect of larger or smaller choke tube? (2.) The effect of increased or diminished number of apertures in spray? (3.) The effect of raising or lowering weight on needle valve? (4.) Would not a small disc of lead placed on top of float have the same effect as lowering weight on valve needle?—A. L. L.-S.

It is quite possible that the failure to respond to the throttle may be due to the cylinder head and piston requiring to be cleaned of carbon deposit. If the carburetter were once right it is unlikely that it has got out of adjustment of its own accord. (1.) If the engine starts easily and takes the full amount of air even when running at slow speeds, and when you open the throttle there is absolutely no difference in power, and there are signs of over-heating, the choke tube is too small and a larger one is necessary. If, however, the machine starts with great difficulty, misses fire, and seems unable to attain its full power with the throttle fully open and spark advanced, too large a choke tube is fitted and a smaller one is required. (2.) The same remarks apply to the jets, but it will often be found that, though the adjustment is apparently correct, there is not quite as much power as might be desired, and sometimes the fitting of a slightly larger jet will improve matters. The whole thing is a matter for careful experiment. (3.) Moving the weight on the needle nearer to the point raises the level of the petrol in the jet. A lead washer slipped on top of the float would have the same effect. What we should recommend you to do is to look up the hints on "Carburetter Adjustment" in "Motor Cycles and How to Manage Them." In this chapter the matter is thoroughly dealt with, and your questions are practically answered. Loss of power, of course, need not always be due to the carburetter, but might possibly be owing to weak compression, worn lifting cams, and to the valve springs being to weak.

Gear Ratio of Track Racer.

A friend and myself are divided in opinion as to what gear ratio C. R. Collier used on his 85 × 60 mm. engined Matchless-J.A.P. with which he won *The Motor Cycle* Challenge Cup, riding 50 miles 858 yards in the hour, last October. We should be glad if you would tell us.—C. V. C.

The gear ratio used by C. R. Collier on the occasion stated was $3\frac{2}{3}$ to 1.

A motor cycle "breakdown" competition — quite an interesting diversion during the winter months arranged by the Liverpool Motor Club. The Premier motor cycle has been deranged, and a competitor (S. W. Carty, late of Newcastle) is endeavouring to put the machine in order against the watch (held by A. J. Moorhouse), S. W. Philpott and E. L. Fehr making notes and conducting the competition.

MORGAN'S PETROL TURBINE.

A Reply to "Incandescent" and V. Grunwell.

I WOULD like to reply to the criticisms of "Incandescent" and Mr. V. Grunwell. The outer shell of the turbine is simply to retain the pressure of the gases in the combustion chambers, the spaces between the vanes being just large enough to carry away the gases to the exhaust slots sufficiently fast to maintain that pressure. I do not rely on the velocity of the gases formed by the combustion, but on the pressure which acts on the base of the combustion chamber. "Incandescent" says that the turbine will not run because the piston has to pump air against the pressure of the combustion.

Now, the volume of air thus pumped is small compared with the volume of the products of combustion, so that the work done in forcing the air into the combustion spaces is much less than the work done by the products of combustion. It is just this difference between the two quantities of work which drives the turbine. There is no doubt that the turbine will work, just as a steam boiler is made to feed itself with water against its own pressure.

The Action of the Eccentric.

"Incandescent" also takes exception to the action of the eccentric on the rollers in the piston. Now while the eccentric is moving the piston forward there is certainly a space between the eccentric and the hindmost roller, but after the piston has moved halfway along the cylinder this distance diminishes, until at the end of the stroke the rear roller is actually in contact with the eccentric, and ready for the pressure of the return stroke. I have not provided for a commutator, but, instead, a complete insulated ring mounted on the drum and connected to the sparking plugs. The electric circuit is completed by an insulated switch mounted on the side plate, which makes contact with the ring when necessary to start the turbine.

Heat Generated and Method of Control.

Mr. Grunwell thinks that the heat generated will be very destructive. Why? The two exhaust slots are very large, occupying together about half the area of the rim of the drum, so that the hot exhaust gases escape easily, immediately, and silently. Of course, the heat lost is very great, but surely this means that the turbine is correspondingly cool. As in ordinary internal combustion engines, it is the pressure that is utilised, not the heat, and that engine is the best which disposes of the heat in the best and quickest way.

With regard to the absence of control over the petrol supply, the demand of the turbine for petrol is purely automatic, depending entirely on the speed of the drum, which is in turn controlled by the throttle. No doubt the turbine could be regulated quite independently of the throttle by means of the main petrol tap.

R. E. MORGAN.

TWO-STROKE ENGINES IN AMERICA.

I HAVE been much interested and pleased to note the progress of the two-stroke engine in England as portrayed by *The Motor Cycle*. Perhaps readers would be interested to hear of my experiences with two-stroke engines in general and two-stroke motor cycle engines in particular.

My first motor cycle had an engine of the four-stroke variety, and was one of the first to be used in California. In 1903 I graduated from the four-stroke to the two-stroke, and I shall never go back to the four-stroke engine on any account.

In 1903 I met a man in Oakland, California, who made two-stroke motor cycles, and I soon became interested and placed an order for one. At that time he only made motor cycles to order, so I had to wait several months for delivery.

As soon as I received my machine I started out for a short trip, but oh! such trouble. For me the machine absolutely refused to go at first, and when it did go it was well nigh impossible to slow it down. However, after the first week of trouble, things began to improve and the machine ran all right.

A Two-stroke Machine in Use since 1903.

This machine has now been running since March 3rd, 1903, and has carried me many thousands of miles, over vile roads or no roads at all, without a bit of trouble. The cost of repairs has been *nil*, as it has never been in a shop. Of course there is absolutely nothing to get out of order in the engine except the rings and bearings, and none of these have ever been removed or replaced.

The belt used is of specially tanned leather, and is round instead of V. Its diameter is about one and one-sixteenth inches, and the belt complete costs about ten dollars (two pounds). This may seem expensive but these belts seem to last for ever. I run my round belt in 28° V pulleys, and have absolutely no slipping even in rainy weather.

A Single-cylinder 7¼ h.p. Engine.

My latest motor bicycle is a 1910 racing model. The cylinder bore and stroke are 3½in. by 3¾in. and the engine develops about 7¼ b.h.p. The wheels are 28in. in diameter, and the engine gear ratio is 2¾ to 1. This engine develops its rated power at 2,500 r.p.m., but can be speeded up to 3,000 r.p.m. if necessary.

Of course, my touring mount is not so big as this. It has a cylinder with a 3in. bore and a 3⅛in. stroke, and only develops about 4 b.h.p. The weight of the machine is about 185 lbs., of which the engine weighs 40 lbs. Personally I like heavy roadster machines, as the lightweight has not the power and speed that I prefer in this country of "no speed limits."

All my machines have single-cylinder engines with dry battery ignition.

California is nearly ideal for motor cycle touring in summer or winter, as we do not know what snow or cold is like.

Some of the most beautiful scenery in the world is to be found in California, and it is not surpassed by Switzerland or any country I have ever visited.

A. N. RAMSAY.

GRADUA GEAR

Infinitely variable and free engine.

Winner of Coventry Hill Climb.
Winner of Barnsley Hill Climb.
Winner of Herts. County Hill Climb.
Winner of Prince's Cop Hill Climb.
Fastest single cylinder variable gear at Sutton Bank.

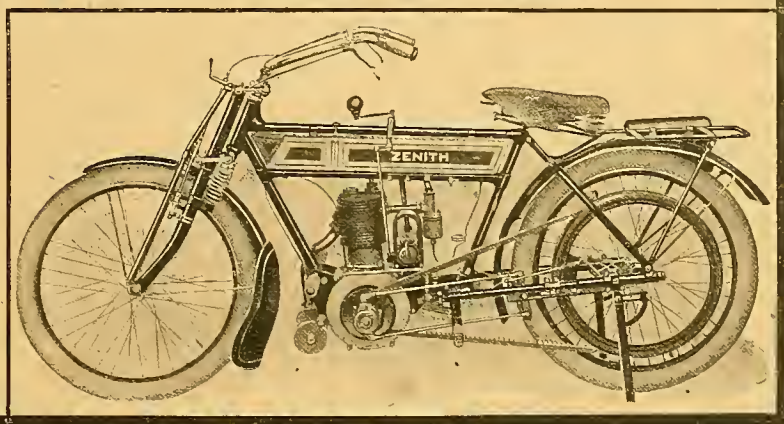
Winner at Brooklands Inter-'Varsity Races.
Holder of Brooklands Test Hill Record.
Full marks for everything A.C.U. 1,000 Miles Trials.
The only gear to carry out an observed traffic ride.
And many other successes.

THE GRADUA GEAR WAS BARRED IN AN /09 HILL CLIMB ON ACCOUNT OF ITS EXTRAORDINARY EFFICIENCY.

The Gradua Gear
is only fitted to
ZENITHS,
and made as a conversion set for
TRIUMPHS.

Full particulars on application.

ZENITH MOTORS, LTD., Weybridge.



THE L.M.C. STARTS LIKE A CAR.

AT HOME SATISFACTION.

London,
Nov. 21st, 1909.

Gentlemen,

I have found the gradient map of our London hillocks. Muswell Hill is where I tried your excellent Free Engine and Pulley. You will see that it is a good test of its efficiency to start a machine from stand still in the middle with rider and luggage weighing 17 stone and to take it up to the top. It is as good a test as you want and your Free Engine can do what a two-speed gear would, and at a fifth of the cost and weight.

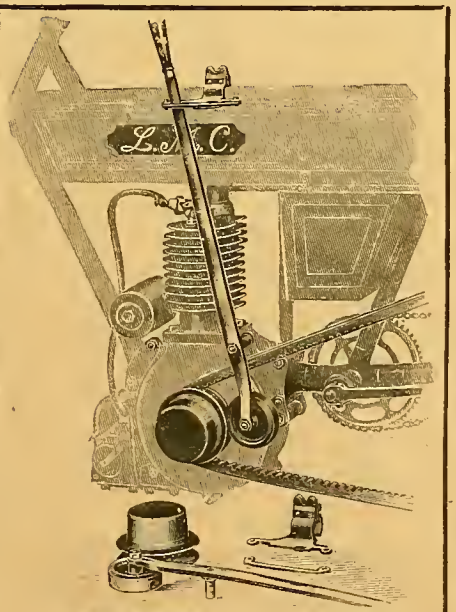
The steepest of the three is Swains Lane. Needless to say the L.M.C. flew up it, in fact I ran up on half throttle except over the steep portion. The machine was in full touring condition and had not had any adjustment for 400 miles. I used standard jet. Highgate of Hill course was nothing to test it. It went up as though it were level ground.

Yours truly,
H.B.

The Ideal Touring Machine.

More practical refinements and improvements than any standard motor bicycle.

Price complete with Free engine, 50 guineas.



L.M.C. FREE ENGINE & AUTO VARIA PULLEY.
(PATENT APPLIED FOR.)
SUITABLE ANY STANDARD ENGINE, Price 63/-

ABROAD RELIABILITY.

The Rectory, Condobolin,
New South Wales,
Australia.
13/12/'09.

Dear Sirs,

I have now ridden my L.M.C. for twelve (12) months over some of the worst roads in New South Wales and in all weathers. I cannot speak too highly of its behaviour. I have not had a single stoppage the whole time. I sometimes ride ninety (90) miles and take three services in the day. Reliability in running is a necessity in my work, as one has to ride against time, allowing very narrow margins for mishaps. I have complete confidence in the L.M.C. motor cycle, and have not the slightest hesitation in recommending it.

Another point in its favour is the smoothness of its running, the vibration being reduced to a minimum.

Yours faithfully,
S. N.

The smoothest running machine made.

Magneto gear driven in dustproof oil bath.

New footboard ball bearing starter.

L.M.C. Machines are designed by Mr. W. J. Lloyd, formerly Mechanical Director of the late Quadrant Cycle Co., Ltd., Birmingham.

The LLOYD MOTOR & ENGINEERING CO., L.M.C. WORKS, 132, Monument Rd., Birmingham.

L.M.C. parts for original Quadrants can be supplied from stock. New List Printing.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns—1d. per word, minimum 1s. Name and address must be counted. In the case of Trade Advertisements a series of thirteen insertions is charged as twelve.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor Street, E.C.), on Tuesday morning previous to the date of issue.

When possible advertisements received at Coventry on the Wednesday will be inserted.

All letters relating to advertisements should state distinctly under what heading and in what issue the announcement appeared.

CLASSIFICATION BY LOCALITY.

For the convenience of purchasers of second-hand motor cycles, the advertisements are classified into districts, as many readers like to know what machines are for sale in their immediate neighbourhood before going further afield.

Plan showing division of England into Sections.

SECTION I.
Northumberland. Cumberland, Durham, and Westmoreland.

SECTION II.
York and Lancashire.

SECTION III.
Carnarvon, Denbigh, Flint, Cheshire, Derby, Stafford, Shropshire, Montgomery, and Merioneth.

SECTION IV.
Nottingham, Lincoln, Leicester, Rutland, Northampton, Warwick.

SECTION V.
Norfolk, Suffolk, Cambridge, Huntingdon, and Bedford.

SECTION VI.
Worcester, Hereford, Radnor, Brecknock, Monmouth, Glamorgan, Carmarthen, Cardigan, and Pembroke.

SECTION VII.
Gloucester, Oxford, Buckingham, Berks, Wilts and Hants, Channel Islands.

SECTION VIII.
Hertford, Essex, Middlesex, Surrey, Kent, and Sussex.

SECTION IX.
Somerset, Devon, Dorset, and Cornwall.

SECTION X
Scotland.

SECTION XI.
Ireland and Isle of Man.

No. 2064.—2½ h.p. 1910 PHELON & MOORE, light weight model, two-speed gear, only once used, not ridden fifty miles; guaranteed ..... 42 Guineas
3¾ h.p. 1910 Twin-cylinder PREMIER, once used only, too powerful for user; guaranteed .. £45 0
No. 2067.—1¾ h.p. 1909 MOTOSACOCHE, magneto ignition, Druid spring forks, condition as new; guaranteed. Price, lowest £24 10
No. 2060.—3½ h.p. T.T. TRIUMPH, 1909 model, nice condition; guaranteed ..... 32 Guineas
No. 2000.—3½ h.p. 1909 PREMIER, as new, horn, mirror, toolbag, tools, and number-plates; guaranteed ..... 30 Gns.
No. 2001.—3½ h.p. 1909 TRIUMPH, standard model, in very good condition ..... 33 Gns.
No. 2002.—3½ h.p. 1909 BAT, spring frame and forks, magneto, Continental non-skid tyres, as new; guaranteed ..... 35 Gns.
No. 1973.—3½ h.p. 1909 TRIUMPH, Clincher studded tyres, usual tools, in excellent condition; guaranteed £35 0
No. 1977.—3½ h.p. 1910 ARNO, magneto, B. and B. handle-bar controlled carburetter, spring forks, Continental non-skid tyres; this machine has only been run twenty miles; guaranteed .. £35 0
No. 1979.—2¾ h.p. Magneto F.N., h.-b. control, spring forks and spring seat, in excellent condition; guaranteed £17 10
No. 1982.—3½ h.p. TRIUMPH, 1908, magneto, h.-b. control, Clincher tyres, in excellent condition; guaranteed £32 0
No. 1941.—3½ h.p. 1909 Standard TRIUMPH, Palmer Cord tyre on front, new Palmer Cord rubber-studded on back, usual tools; guaranteed £36 0
No. 1952.—3½-4 h.p. BAT Racer, M.O.V., magneto, 1909, one of the fastest 3½ h.p. machines ever been raced on Brooklands, fitted with Cowey speedometer, lately the property of H. H. Bowen; guaranteed £28 0
No. 1961.—3½ h.p. 1907 TRIUMPH 1908 engine, magneto, Roc two-speed gear, lamps, horn, etc., in first-class condition; guaranteed ..... 30 Gns.
No. 1967.—3¾ h.p. N.S.U., magneto, 26in. wheels, good tyres, engine, enamel and plating as new; guaranteed ..... 20 Gns.
No. 1926.—3½ h.p. VINDEC SPECIAL, magneto, Truffault forks, Peugeot engine; guaranteed .. £25 0
No. 2032.—2 h.p. New 1909 Standard MOTO-REVE 28 Gns.
No. 2033.—5 h.p. VINDEC, Roc two-speed gear, magneto, lamp, horn, two toolbags, pump, enamelled cream, smart machine ..... 28 Gns.
No. 2006.—5 h.p. 1908 TWIN VINDEC, rubber-studded tyres, magneto, adjustable pulley, toolbag, tools, and horn; guaranteed £25 0
No. 2007.—3½ h.p. BROWN, Whittle belt, long bars, low seat, horn, toolbag, etc.; guaranteed 10 Gns.
No. 2010.—3½ h.p. N.S.U., magneto, h.-b. control, spring forks, good tyres, horn, toolbag, and spare belt; guaranteed ..... 18 Gns.
No. 2011.—5-6 h.p. A.C. Tricar, 1909 model, with lamps, horn, and apron, as new ..... Offers
No. 2014.—3½ h.p. Bat-engined Motor Cycle, Chater-Lea No. 6 frame, round brass tanks, footboards, Continental tyres, very smart machine; guaran'd £15 0
No. 2018.—2¾ h.p. WHITLEY, vertical engine, 26in. wheels, low frame; guaranteed £6 10
No. 2019.—3½ h.p. 4-cyl. F.N., good tyres, enamel, plating, engine, etc., perfect; guaranteed £20 0
No. 2021.—3½-4 h.p. MATCHLESS J.A.P., overhead valves, magneto, J.A.P. carburetter, Druid forks, good tyres, footrests, horn, toolbag, carrier, and stand, as new; guaranteed ..... 28 Gns.
No. 2013.—3½ h.p. 1909 TRIUMPH, standard model, excellent condition, with Cowey speedometer; guaranteed £38 0
No. 2024.—3½ h.p. 1909 MINERVA, magneto, spring forks, in very good condition; guaranteed £25 0
No. 2025.—5 h.p. RILEY Tricar, open frame, wheel steering, two speeds, quantity of spares, three lamps, horn, etc., a very smart lot; guaranteed £38 0
No. 1993.—2¾ h.p. Genuine DE DION BAT, good tyres, lamp, horn, speedometer, toolbag, and tools; guaranteed £12 10
No. 1994.—3½ h.p. 1909 TRIUMPH, Clincher non-skid tyres, Mabon free engine, horn, spare belt and spare adjustable pulley; guaranteed ..... 36 Gns.
No. 2027.—3½ h.p. New 1909 Standard EXCELSIOR; guaranteed £37 10

Machines offered in this column are guaranteed by Wauchope's.

First Cheque secures each Bargain.

WAUCHOPE'S,

9, Shoe Lane, Fleet Street, LONDON, E.C.

Phone: 5,777 Holborn. Telegrams: "Opificer, London."

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may addressed to numbers at "The Motor Cycle" Off When this is desired, 2d. will be charged for registrat and three stamped and addressed envelopes must be s for forwarding replies. Only the number will appea the advertisement. Replies should be addressed, " ooo, c/o 'The Motor Cycle,' Coventry"; or if "Londo is added to the address, then to the number given, "The Motor Cycle," 20, Tudor Street, E.C.

DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown pers may deal in perfect safety by availing themselves of Deposit System. If the money be deposited with "' Motor Cycle," both parties are advised of this receipt, upon intimation of the arrival and acceptance of goods, the money is forwarded less a charge of 1s. registration. The time allowed for a decision after rec of the goods is three days, and if no sale is effected, e party to the transaction pays carriage one way. For transactions exceeding £10 in value, a deposit fee 2s. 6d. is charged. All deposit matters are dealt w at Coventry, an: cheques and money orders should made payable to Iliffe and Sons Limited.

SPECIAL NOTE.

Readers who reply to advertisements and receive answer to their enquiries are requested to regard silence as an indication that the goods advertised h already been disposed of. Advertisers often receive many enquiries that it is quite impossible to reply to e one by post.

MOTOR BICYCLES FOR SALE

SECTION I.

Northumberland, Cumberland, Durham, a Westmoreland.

MINERVA Motor Cycle, 3h.p., good running or £11, or best offer.—Walker Bros., Cockermo

3h.p. Fafnir Motor Cycle, new tyres, long handle-b low seat-pillar, footboards, climb anything, gua teed perfect, tools, etc.; £17.—Todd, Wolsingham, D ham.

SECTION II.

York and Lancashire.

1909 Triumph, good as new; £39.—Sproat, Raw Leeds.

5½h.p. Twin N.S.U., magneto, spring forks; £14 Horner, 28, Burley Rd., Leeds.

3½h.p. P. and M., 1908, in splendid order; £30.— 3,998, *The Motor Cycle* Offices, Coventry.

1910 Twin Premier, new; £45; cash with order; exchanges.—Evic Cycle Co., Whittingham, Pres

1909 Brown, 3½h.p., magneto, handle-bar control, condition; £29.—Cross, Triumph Agent, Rot ham

7h.p. Peugeot Druids, Brown and Barlow H.B. trol, perfect; £23.—Hall, 26, Oxford Rd., Wate Liverpool.

PHELON and Moore, 1908, 3½h.p., H.B. control good condition, spares; £32.—Dearlove, The Harrogate.

1910 Triumphs, unerated; £45 15s., cash order; no exchanges.—Evic Cycle Co., Whitt ham, Preston.

3½h.p. Rex, fast, reliable, condition as new; £1 Anderson, 846, Chester Rd., Gorse Hill, Stret Manchester.

FOR Sale, two 1908 Triumphs, in first-class co tion.—For particulars, apply J. L. Balmf Ormskirk, Lancs.

HALIFAX.—Rex motor cycles, 100 to select fr £8 to £75; special list on application — M Exchange, Westgate, Halifax.

MANCHESTER Motorists can obtain Ariel, I bury, Douglas, Norton, R.M.C. two-stroke official agent, Gourlay, Fallowfield.

A FEW 1909 New Bradbury 3½h.p. Motor Cycles, one 1908 Bradbury, 3½h.p., accumulator igni perfect order, £18.

3½h.p. Minerva, with Phœnix two-speed gear, an sidecar machine; £20.

GOOD 3½h.p. Minerva, perfect condition; £16.

GOOD 3½h.p. Bat Tricar, very handy machine: £

GOOD Stock of Tyres, tubes, belts, horns, etc.

SOLE Agent for the famous Bradburys; good allow for old machines in exchange.—Parry, 68, G St., Oldham.

OTOR BICYCLES FOR SALE.

DION-BAT, magneto, Palmer tyres, low build, fast, and reliable; £15.—Hall, Colville Dairy, Talbot, W.

BLE, 3h.p., M.O.V., good running order; sell or exchange; £6 10s.—S. Green, 145, Manor Rd., ley.

1909 J.A.P., 4h.p., M.O.V., J.A.P. adjustable ley, Bosch magneto, Chater frame and s forks, Palmer tyres, H.B. control not done 300 including accessories; £32.—Below.

1908 J.A.P., 4h.p., Bosch magneto, Chater f Druid spring forks, footboards, studded Autoclipse lamp, etc.; £26.—Below.

1909 F.N., 4-cyl., F.N. footrests, H.B. co R.O.M. combination tyre, with nearly new car; £35.—Below.

1909 Peugeot, 5h.p., Chater, adjustable p R.O.M. and Palmer cord covers, Dav gauges and fillers, F.R.S. lamp; £20.—Below.

1909 Minerva, 3½h.p., entire handle-bar control, neto, spring forks, Amac carburetter, grey condition perfect; £26.—Below.

1906 Minerva, 2¾h.p., Bowden H.B. control, p order, guaranteed; £12.—Below.

1907 De Dion, 2¾h.p., spring forks, rubber st tyre, light low machine, splendid cond spares; £12.—Below.

IN addition to the above the Eastern Garage Co a number of machines at prices ranging fro Please favour us with a visit at 418, Romford Forest Gate, or telephone, Stratford 10. Tele Egaraco, London.

2½h.p. Century Lightweight, perfect, £5; 3½h.p nir, new tyres, £14; 3½h.p. M.M.C.-Bat, 4¾h.p. Stevens, Osborne four-speed complete, with built sidecar, £17.—Smith, 16, Triangle, Bishop's Fulham.

4-CYL. F.N., perfect condition, footboards, fo celerator, automatic carburetter, adjustable je proved induction pipe, and silencer, new Dunlop Englebert front, lamp, tools, spares, etc.; £22.—J 12, Grotto Rd., Twickenham.

CLEARANCE.—2¾h.p. Kerry, £8 10s.; 6h.p. twi toine, £17 10s.; 2¾h.p. Brown, £8 10s.; Quadrant, £4 10s.; 2¾h.p. J.A.P., £8 10s.; 2¾h.p. mix, magneto, two speeds, £14 10s.; exchanges; call, or write; trials.—128, High Rd., Tottenham. 1982, Tottenham.

3½h.p. Minerva, new six months ago, not ridde miles, absolutely perfect, two accumulators by new rigid device, no terminals to fix), Mabon and pulley, Continentals, carrier, stand, and all s £25 cash, a real bargain; any evening by appointm S. Blenkarn, 58, Cromwell Rd., Beckenham.

8h.p. Minerva, £25; 4½h.p. Minerva, £20; fore fit either machine, 90s.; 2¾h.p. Minerva, £1 h.p. magneto F.N. lightweight, £20; Motosacoche, Rover forecar, £18; 3h.p. Quadrant, vertical e spring forks, low frame, £12; 8h.p. Buchet pacing £35; sidecar, £4.—Seen at, or further particulars The Cripps Cycle and Motor Co., 24-28, Woodfor Forest Gate, London, E. Tel.: 75 Stratford.

COMPLETE Outfit.—3½h.p. Minerva, nearly new tinental, Palmer cord, unpunctured, Lycett and carrier, Lyso belt, Price's stand, G. and A. matic h.b.c., voltmeter, Autoclipse lamp and gen spare belt, plug, valves, chain, pulley, etc., all ne numerous spare parts, etc.; expert examination in receipts shown; trial; purchaser need buy nothing £18 10s.—S. Perkins, 161, High Holborn, W.C.

SECTION IX.

Somerset, Devon, Dorset, and Cornwall

TRIUMPH and Motosacoche, 1910 models in cash, exchange, deferred payments.—Dar Weymouth.

4h.p. 2-cyl. Motor Bicycle, Kerry engine, thor first-class condition, cheap for cash, or s exchange.—Geo. Pollard and Co., Ltd., Taunton.

QUADRANT, 3½h.p., 1910 model, equal new, g teed; £38; approval; deposit; or exchange Douglas.—P. Thorne, Brunswick, Tiverton.

TWIN Vindec, Truffault, spring forks, magneto speed gear, free engine, 2¾in. tyres, stand carrier, tyres, tubes, and engine perfect, with rigid ford sidecar, 2½ tyre; £37, or offer.—Dan Guy mouth.

In answering these advertisements it is desirable to mention "The Motor Cycle."

THE MOTOR CYCLE SUPPLEMENT

THE TOURIST TROPHY RACE.

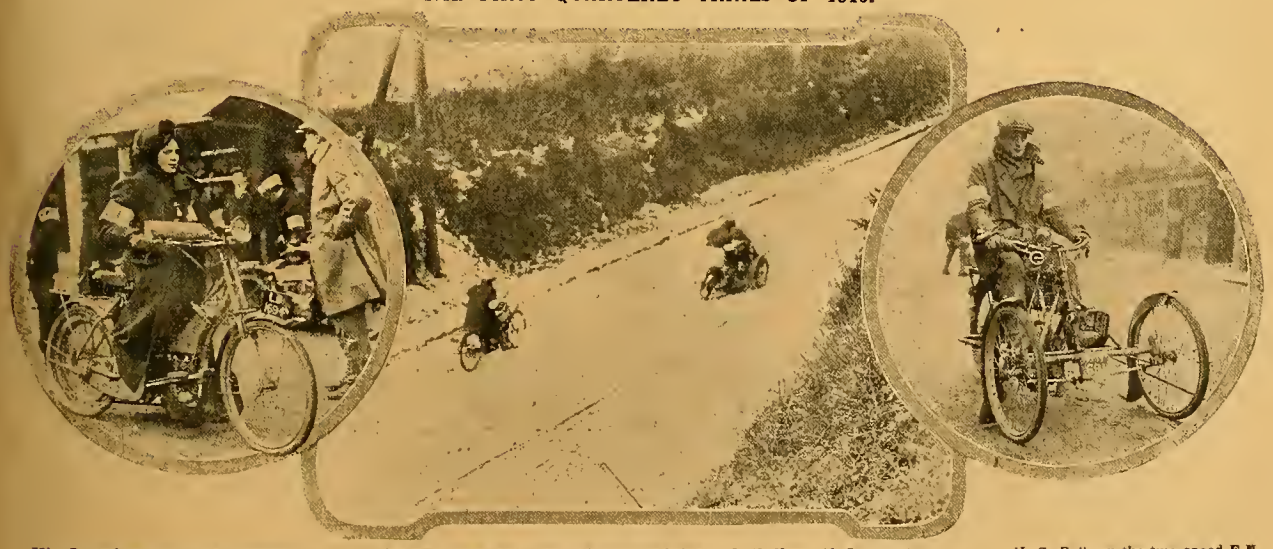
THE following is a list of the entries received to date for the International Tourist Trophy Race, to be held on Thursday, May 26th:

H. A. Collier, winner 1909 (1 Matchless).
W. H. Wells (2 Indians).
Hendee Manufacturing Co. (3 Indians).
W. O. Bentley (1 Indian).
Triumph Cycle Co. (3 Triumphs).
C. B. Franklin (1 machine).
Noel E. Drury (1 machine).
H. Collier and Sons (2 Matchless).
Quadrant Motor Co. (1 Quadrant).
Rex Motor Manufacturing Co. (3 Rex).
Scott Engineering Co. (1 two-stroke Scott).
W. H. Bashall (1 Bat-J.A.P.)
J. T. Bashall (1 machine).
H. H. Bowen (1 Indian).
Norton Manufacturing Co. (1 Norton).
S. A. M. Whitham (1 Triumph).

THE SAFETY OF THE HIGH ROADS.

A CASE of considerable importance to owners of motor cycles has been settled by Judge Lumley Smith, K.C., and a jury. The jury in question decided that if any person takes up a high road it is his duty to leave the whole of it so that it is safe for all forms of road traffic. In the case referred to, Messrs. Fremlin Bros., brewers, sought to recover £16 14s. 11d. from the Rayleigh Gas Co. for damage done to a motor lorry on Weir Hill, Rayleigh, in September last. Messrs. Fremlin Bros. consulted the Legal Department of the Motor Union, and on their advice Mr. Moresby White was briefed. The plaintiffs' case was that the wheel of one of their motor lorries, in passing over a portion of the road, sank up to the axle into a newly-filled trench, cutting the twin tyres to pieces. The defendants maintained that the driver of the lorry should have avoided that section of the road, as it was obvious that the trench had but recently been filled up. The company had been laying gas mains, and the road was hand-rammed. Judge Lumley Smith, however, stated that it was the duty of anyone who disturbed the high road, afterwards to leave the whole of it in safe condition for all ordinary traffic; or if, as the defendants contended, wet weather prevented the newly-laid portion from hardening, it ought to be kept safe, and steps should be taken to warn traffic of its unsafe condition. There was nothing to show that the plaintiffs' lorry was of extraordinary weight. This decision tends to prove that county councils are liable for any damage caused by leaving unrolled stones on the road at night without a warning light.

THE FIRST QUARTERLY TRIALS OF 1910.



Miss Berend starting from Uxbridge on her Moto-Reve lightweight.

Climbing Dashwood under adverse conditions: G. N. Higgs (A.C. tricar) and G. H. Lake (P. and M.)

H. G. Bell, on the two-speed F.N. tricycle. This is the first tricycle to complete the trial.

Motor Cycles in the Army.

The above is the title of a lecture which Capt. Battine has kindly undertaken to deliver before the A.C.U. at an early date, probably this month.

Motorists' Sympathy.

The Motor Union has voted the sum of 500 francs towards the relief of the distress caused by the recent disastrous floods in Paris.

New and Old Pattern Machine in the Trial.

There was only one 1910 Rex in the Quarterly Trial. This was ridden by F. A. Applebee, jun., who accomplished a non-stop. The machine ridden by F. W. Applebee, sen., was a 1908 pattern.

The New York Show.

The undermentioned figures, which refer to the motor cycles exhibited at the recent New York Show, show the tendencies and developments in American motor cycle design better than pages of description. The census was compiled by the *Bicycling World*.

Climbing Hills in "less than no time."

A N.S.W. motor cycle club recently held a hill-climbing competition on a rise one mile in length on a handicap basis, but a rider of a Motosacoche was too generously treated by the handicappers, for it was found that by dint of vigorous pedalling he had actually reached the summit before his competitor had started! To have won, the Motosacoche rider's rival would have had to climb the hill "in less than no time," to use a colloquialism.

Annual Dinner of the R.A.C. and Associate Clubs.

The annual dinner of the R.A.C. and Associated Clubs took place on Thursday last at the Connaught Rooms, Great Queen Street, W.C. The dinner is of interest to motor cyclists chiefly on account of the Auto Cycle Union being one of the most important bodies affiliated to the R.A.C. Moreover, Mr. Robert Todd, the chairman of the A.C.U.; Mr. F. Straight, the secretary; and other prominent members were present. The Hon. Arthur Stanley, M.P., was chairman in lieu of Prince Francis of Teck, K.C.V.O., D.S.O., president of the A.C.U., who was unavoidably absent, but his brother, Prince Alexander of Teck, K.C.V.O., D.S.O., sat on the chairman's right. The royal toasts were proposed by the Chairman, and that of "Automobilism" by Sir Henry Norman. Lord Montagu, in his reply, mentioned that in future it was necessary to devote more attention to the roads, and to endeavour to improve them as regards dustlessness, surface, and to straighten out their curves. Mr. A. Armitage, J.P., in proposing the "Houses of Parliament," said he hoped that the Act, which was after all not such a bad Act, would be interpreted in a sensible manner. So often the treatment of motorists was different in the Petty Sessional from what it was in the police courts. The Earl of Clarendon and Lord Claud Hamilton replied to the toast, and the latter expressed it as his opinion that it was most inadvisable to impose a tax upon a thriving industry, and a tax such as the petrol tax was prejudicial to home productions. The toast of "The Chairman" was proposed by Sir Edward Henry, Commissioner of Police for the Metropolis, and was replied to by the Hon. Arthur Stanley and Prince Alexander of Teck.

News from the Clubs

The doings of thirty-four clubs, representing many thousand motor cyclists, are recorded in this issue.

Bolton and District M.C.

"Magneto Ignition" was the subject of a lantern lecture delivered by Mr. E. Bennett on Wednesday evening last to a company who assembled at the annual dinner and social of the above club. The attendance numbered sixty.

Pneumatic Helmets.

The value of a racing casque or pneumatic helmet has been brought before our readers on many occasions, and there are several riders who owe their lives to their forethought in providing themselves with what is undoubtedly the best cyclist's life protector. On the subject of the use of a helmet is insisted on, and it would be in the interests of the pastime if the A.C.U. would embody in the regulations that a casque should always be worn.

The T.T. Race Sanctioned.

Last Tuesday a telegram was received by the A.C.U. granting official permission of the Highway Board of the Isle of Man to hold the International Motor Cycle Tourist Trophy Race on Thursday, May 26th.

Swiss Motor Cyclists' Ideal Mount.

The Swiss Automobile Club is the authority from which we have gathered the following information: "We use lightweight motor bicycles, the weight of which is not over forty kilogrammes, or power more than 2 h.p., such as the Moto-Rêve and Motosacoche, in all weathers, almost like pedal bicycles. These small light machines are extremely strong and lasting, and enable their owners to tour as much as 200 to 300 kilometres a day. The writer accomplished in September last the distance between Geneva and Nîmes, about 400 kilometres, on a 2 h.p. Moto-Rêve, weighing in running order thirty-nine kilogrammes, without the slightest mishap or trouble. The heavy motor cycle has been almost completely given up in Switzerland, as it has been found to be too heavy and unwieldy, apt to skid, dangerous, and costly to maintain."

Affiliation to the Governing Body.

Apparently all is not well in the Nottingham and District Motor Cycle Club's ranks concerning the A.C.U. A proposal was put forward at the recent A.G.M. not to re-affiliate, but it was ultimately decided to continue affiliation for another six months. Nottingham was made one of the A.C.U. local centres at the time the scheme was launched.

The General Meeting of Northern Motor Cycle Clubs.

Arrangements are now being made for the annual meeting of motor cycle clubs at Richmond (Yorkshire) on Good Friday next, and we are asked by the hon. sec. of the 1910 meet, Mr. Geoffrey W. Liddle, of 367, Linthorpe Road, Middlesbrough, to request all Northern club secretaries interested in this meeting to forward their names and addresses to him. Some months ago Mr. Liddle was concerned in an unfortunate accident, which has debarred him from motoring since, and he has therefore got somewhat out of touch with the meeting. Hence his appeal to *The Motor Cycle*.

Quarterly Trials Entries Analysed.

The power of the competing machines ranged from 1½ h.p. to 8 h.p. Forty of the seventy-four machines entered had single-cylinder engines, and the remaining thirty had twin-cylinder engines.

West Essex A.C.

The fifth annual dinner at the Great Eastern Hotel, Liverpool Street, was well attended. The toast list was short, and the speeches bright and brief. The club was founded in 1905, and has enjoyed five years' unchecked progress. During the evening the prizes won in competition were presented by Mrs. Foster Wickens.

The End-to-end Trials.

Additional entries received for the A.C.U. Six Days' End-to-end Trials in July are: W. H., J. T., and H. B. T. Basball (Bat-J.A.P.'s), F. Dover (3½ h.p. Triumph), S. Stacey (3½ h.p. Triumph), and W. H. Wells (2 Indians).

Cambridge University M.C.C.

A general meeting was held at the Blue Boar Hotel on Monday last. It was decided to circularise all members of the club as to the best date for a meeting at Brooklands against Oxford. Also to present a silver cup to the member who made the most attendances at club runs. The silver medal awarded last term for the competition was settled upon, and it was decided to standardise it for all competitions.

Next Saturday the club run is to Bedford.

Hard Luck!

Messrs. E. J. Skinner and J. Trevor, members of the N.S.W. Auto Union, suffered misfortune on a recent Sunday. While out on two valuable motor cycles, they reached Bobbin Head, some miles north of Sydney. Leaving their machines a little off the road, they scrambled down the cliff to have a swim in the briny. Returning an hour later, to their dismay it was found that a bush fire had swept part of the surrounding bush, and every inflammable part of their machines was reduced to ashes. Some picnickers who were noticed near by were most likely responsible for starting the fire.

(SEE ALSO PAGE 99.)

CLUB NEWS.

(SEE ALSO PAGE 99.)

Bristol Bicycle and M.C.

Members of the motor section are asked to attend a meeting at headquarters to-morrow (Tuesday) at 8 p.m.

Essex M.C.

Mr. A. E. Lowe's paper on "The History of the Internal Combustion Engine" has been postponed until Thursday, the 17th inst.

Sheffield and Hallamshire M.C.C.

Next Thursday is set aside for Messrs. D. Bradbury's and J. Haslam's lecture night on "Transmission" and "Magnetos." Commence at 8 p.m.

Streatham and District M.C.C.

Fixtures for 1910 are as follows: April 16th, hill-climb; May 7th, reliability trial; June 11th, petrol consumption test; June 18th, gymkhana and garden party; September 17th, hill-climb.

Hertfordshire County A.C. (Motor Cycle Section).

The Triumph Cycle Co., Ltd., Coventry, have very kindly presented to the Hertfordshire County M.C.C. a handsome challenge cup for open competition during the present year.

Leeds M.C.C.

The annual general meeting of the above club was held last Monday evening, and was well attended. The following is the list of officials elected for 1910: President, Rowland Winn; vice-presidents, H. A. Hughes, H. Archer, J. R. Kelly, J. Whittle, O. Brooks, A. I. Greenwood, W. D. Brown, E. S. Myers, H. Wheater, and F. Scriven; committee, J. Scriven, P. H. Cockroft, F. W. Greenwood, G. Horner, F. C. Bagshaw, J. W. Fawcett, H. Murphy, H. D. Shaw, W. A. Andrews, and F. Mackay; press secretary, F. C. Bagshaw, 4, Ash Grove, Headingley, Leeds; trials hon. secretaries, F. O. and F. K. Langton, Call Lane, Leeds; hon. treasurer, W. Grinstead, Victoria Arcade, Leeds; hon. secretary, A. Matthews, Triumph Depot, King Edward Street, Leeds; hon. auditor, C. P. Wilson; hon. solicitor, H. Broadbent.

North-west London M.C.C.

The whist drive on Wednesday, most ably conducted by Mr. Williams, was splendidly supported by members and their friends, seventy of whom attended. Mr. Bate, the new vice-captain, will present a prize for the best attendance at social meets held during the riding season.

Will members who intend to take part in the billiard handicap communicate with Mr. T. G. Blundell at once?

Purley and District M.C.C.

The annual general meeting will be held at Wilson's Café, the tram terminus, Purley, on the 16th inst., at 7.30 p.m.

Batley and District M.C.C.

A good muster of local riders attended a meeting at the Central Café, Commercial Street, Batley, when it was decided to form a club to be known as above. The subscription was fixed at 7s. 6d., no entrance fee to be charged. Mr. H. H. Mann was elected hon. sec.

Cardiff M.C.

The sixth annual meeting was held at the Park Hotel, Mr. H. Haddon (chairman of committee) presiding. The annual report and statement of accounts for the year ended December 31st were adopted.

The secretary's report for the year 1909 states: "The club has again had a most successful year. There are no liabilities, and the funds are on the credit side. The membership has increased to over 100."

FUTURE EVENTS.

Feb. 18-26—Manchester Motor Cycle Show, City Exhibition Hall, Deansgate
Mar. 12—M.C.C. Opening Run.

" 28—A.C.U. Open Hill-climb.

Scarborough and District M.C.

On the 27th ult. Mr. H. Frain read a paper on "Clu Competitions." There was a good audience, and the pap was well received. Previous to the reading, a series slides, illustrating the A.C.U. Sutton Bank hill-climb, t Tourist Trophy Race, and the M.C.C. run to Land's En were shown.

Keighley and District A.C.C.

The first general meeting of this recently formed clu will be held in the Victoria Hotel, Cavendish Street, Tuesday, February 15th, at 7.30 p.m. The business wi be to enrol members, elect officers, etc. A smoking conce has been arranged, and all interested in motor cycles a cordially invited to be present.

The British Motor Cycle Racing Club.

In our last issue it was mentioned that the 1910 cor mittee of the above club consisted of Major Lloyd, Messr Straight, Tessier, Hardy, and Pratt. These were t members who were elected to fill the vacancies of those last year's committee who had retired, and in addition the above, Messrs. Ebblewhite, O. L. Summers, A. G. Foste H. H. Collier, and W. H. Wells, are committee members.

Birmingham M.C.C.

The seventh annual dinner was held at headquarters, t Imperial Hotel, on the 29th ult. Son forty to fifty members sat down to excellent repast, which was follow by a musical programme and exhibiti of prestidigitation.

Mr. J. R. Bedford (vice-presiden took the chair, and presented t prizes which had been won durin 1909, comprising the President's (M H. Austin's) silver cup, eleven silv and gold medals, and four prizes ea value £1, together with several oth smaller prizes.

A somewhat lengthy toast list w gone through, and in responding the toast of "The Club" Mr. Vernon C. Brook, the hon. secretar mentioned that the membership h increased some twenty per cent. durin the last twelve months, and there w now a membership of close on hundred.

Mr. H. R. Lane, hon. secretary the Sutton Coldfield A.C., in proposi the toast, mentioned the good feelin that existed between the clubs in t Midlands, and suggested that inter-cl competitions should be arranged in the future.

Mr. Brook pointed out that the Birmingham club h already arranged a competition with the Oxford club on t same lines as last year, and could see no reason why a simil competition should not be arranged with Mr. Lane's club.

Mr. J. Hubbard, responding to the toast of "The Visitors which had been ably proposed by Mr. Duke (captain), ga some reminiscences of his early experiences with motor cycl

Proposed Newport and District (Mon.) Motor Cycle Club.

The first meeting will be held at the Queen's Hotel Saturday next at 7 p.m., when all motor cyclists in t locality are requested to make a special effort to attend.

Coventry and Warwickshire M.C.

The annual dinner will be held at St. Mary's Hall, Co entry, on Friday next at 6.30 p.m. Colonel Wyley, V.I will preside, and the vice-chairmen will be Messrs. V. Holroyd and John V. Pugh, J.P. Invitations have be issued to the Mayor of Coventry and to Mr. Kenneth Foste the successful parliamentary candidate. Tickets are 6s. eac During the evening the prizes won in 1909 will be present by the chairman.

ADDRESS—20. TUDOR STREET, LONDON, E.C.

Variably Geared Lightweights.

A CORRESPONDENT this week is amazed at what he calls the surprising performances of an "air-cooled teacup motor" fitted to a machine owned by a motor cyclist in his district, who, to use his own words, "calmly drifts up local gradients that stop dead four-fifths of the local heavyweights and 3½ h.p.'s." This marvellous little hill-climber is, it appears, provided with a two-speed gear, which enables it to ascend stiff hills at a fair speed without recourse to pedal assistance. Our correspondent asks, "Are motor cycle manufacturers retrogressive, and shall we eventually come to traction engines?" This is, of course, a little mild sarcasm at the expense of the heavier types of single-geared machine, which are very much in the majority, a comparatively few machines being fitted with change speed gear. However, variable gears of all kinds are slowly but surely increasing in popularity, and as soon as there is a gear which can be fitted to all and sundry existing machines without structural alterations or materially increasing weight and price, then they will be universal, and no motor cycle will be considered complete without one. Although there are several patterns of variable gears on the market suitable for belt, chain, and even gear transmission, most of them have been designed to suit standard models, *i.e.*, machines of 3½ h.p. to 4 h.p., weighing about 160-170 lbs., but very few have been made suitable for lightweights. If anything, the lightweight motor bicycle requires a variable gear more than any other type, and it is also particularly suitable for a change speed attachment, because the low power of the engine permits of a very light compact gear being designed which would enable any reasonably laden lightweight to climb any main road hill with a single figure gradient without pedal assistance.

Nothing would increase the popularity of this type of machine more than a good variable gear, and we hope and expect to see more of them equipped with an emergency gear in the near future.

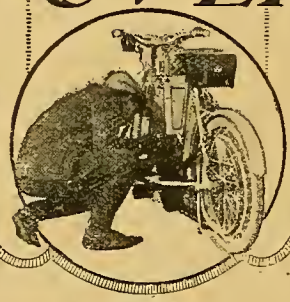
Horse-power and Cubical Capacity.

THE diversity of opinion with regard to the horse-power obtainable from a given cubical capacity is surprising. We have many times referred to this subject, and it is annually brought to the immediate notice of our readers by means of "The Buyers' Guide." We must say we sympathise to some extent with prospective purchasers of motor cycles who read in the columns of the Guide that single-cylinder engines varying from 80 mm. bore to over 87 mm. bore (without taking stroke into consideration) are all reckoned as 3½ h.p. Obviously some must be over and some under this apparently magical horse-power, which is the popular catalogue description given to most single-cylinder engines of greatly diverse dimensions.

If manufacturers would agree to reckon power on cubical capacity; then purchasers would have something more definite to guide their choice. For example, but without any idea of suggesting the actual dimensions, engines from 350 to 400 cc. might be reckoned as 3 h.p., up to 450 cc. 3½ h.p., 500 cc. 4 h.p., and so on.

This calls to mind another suggestion, viz., that our governing body might define horse-power by adopting a formula like the R.A.C. has done for car engines.

How to Overhaul a Motor Cycle



By CON-ROD.

IN the following article it is my intention to show readers who are interested how to set about a complete overhaul of their motor cycles—not only the engine and accessories, but the various parts of the cycle itself, including a few hints on the care of tyres and belts.

There are one or two jobs, such as vulcanising outer covers and inner tubes and enamelling frames, which are usually sent out to be done, but the majority of the easier adjustments can be tackled at home with the aid of a few tools which many motor cyclists possess.

At the outset a fair number of tins should be provided ranging in size from two-ounce tobacco tins to ordinary coffee canisters. These are used as receptacles for the various nuts, screws, balls, and clips, and loss and confusion are avoided. If the tins be watertight so much the better, as paraffin can then be poured on to the parts, when a little judicious shaking will work wonders in freeing them from oil-soaked mud, rust, and grit.

Before dismantling any part of the machine it is advisable to pour about a quarter-pint of paraffin into the crank case through the oil inlet, then, having stopped this up with a plug of wood, pedal or otherwise revolve the engine vigorously on the stand. This will release a very great part of the congealed and half-burnt oil in the crank case and on the under side of the piston. Remove the drain plug and allow the dirty oil to escape. The dismantling process may now begin in earnest.

Silencer and Exhaust Pipe.

Detach all wires and controlling levers, placing the nuts and screws in their appointed tins, and disconnect the silencer and exhaust pipe. These, if already of the right proportions, need not be altered except to clean them. The pipes are generally easily attended to, but if there should be any trouble owing to bends, the pipe may be cleaned by filling it about one-third full of small pieces of grit and then shaking it well. The silencer itself is best cleaned by putting it bodily in the fire and allowing it to attain a fairly bright red heat. When cool the dirt can be removed easily by tapping or brushing. This does not apply to copper or brass silencers, which should be cleaned by scraping only. If back pressure be suspected the capacity of the existing holes in the silencer may be considerably increased by rounding off the edges of the holes on the inside of the plates as at A (fig. 1). These are very often roughly drilled or punched, with the result that a burr is left on the edges, which considerably impedes the passage of gas by causing eddies at this point B (fig. 1). Probably there may be a slight increase in the volume of sound, but it will be hardly appreciable. A tool for rounding the edges is readily made out of a bradawl or small screwdriver by filing a curved shoulder on the broad part as at D (fig. 1), the width at E being the same as the diameter of the existing holes. Finally, the pipe and silencer, after being thoroughly cleaned and rubbed down with emery cloth should receive a coat of dead black paint, such as Radiolene or similar paint sold for cylinders. They will then be ready for fitting up again. A polished exhaust pipe or silencer is a mistake, as bright surfaces do not radiate the heat as well as dead black ones.

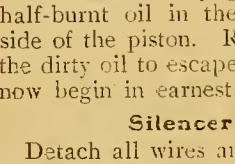


Fig. 1.—Removing burr on silencer holes.
A. Hole after being reamered out.
B. Hole with burr.
C. Tool for removing burr.
D. Cutting edge.

Frame and Forks.

After removing the tank, engine, front and back wheels, etc., strip the frame of all detachable parts including the mudguards, not forgetting to remove the top and bottom ball races from the head. These should be marked, as sometimes they are not interchangeable. The frame and forks should now have the old enamel burnt off, and this may be done either with the aid of a good gas stove or a painter's benzolene lamp. It is by no means such a long job as it might appear at first sight if one be provided with a scraper of suitable shape. This may be made out of a piece of sheet steel about 8in. long by 2in. wide bent to a right angle about 1in. from one end. This part should have a semicircle filed out of it $\frac{1}{32}$in larger than the top tube of the frame. With this the burnt enamel may be peeled off in double quick time. The frame and forks should then be well rubbed down with fine emery cloth and a careful inspection made to detect any fractures in the tubes. This may also be checked by suspending the parts from a peg or wire and "ringing" them—that is, rap the tubes with a key or any other small metal article which is handy, and note the sound given out. If this be sharp and hard and has a ring about it the tubes and joints are all right, but if a dull, jarring sound be emitted it is a sure sign that there is a fracture somewhere, and the faulty part must, of necessity, be replaced or repaired. The re-enamelling may very well be done

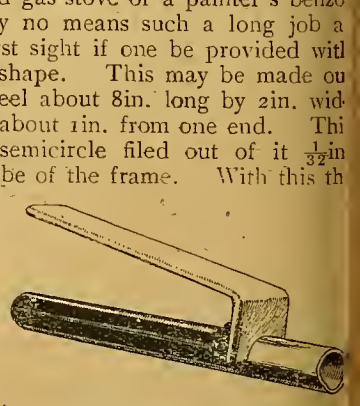

Fig. 2.—Scraping the burnt enamel off the frame tubes by means of a specially shaped scraper.

How to Overhaul a Motor Cycle.—

at home by using an enamel which does not require stoving. It possesses the advantage of not "chipping," but will not look so brilliant after a few months' use as the stoved variety, the reason being that it is not hard enough to resist the grinding effect of removing mud. Should the mudguards show signs of breaking away at the points where they are attached to the back and chain stay bridges, fit a thin steel plate on the inside the full width of the guard and about 6in. long, allowing the bolts to pass through suitable holes placed near the middle of the plate and fitting large curved washers under the nuts.

Covers and Tubes.

With regard to tyre covers, the usual means for filling up cuts in the tread are so well known that they hardly need be mentioned here. Suffice it to say that it is imperative that water should not be able to reach the canvas through any cuts in the rubber. These should have solution well rubbed in, with the cover bent so as to open the cut and allow it to get well down to the canvas. Then, unless they are so otherwise damaged as to need the attentions of a vulcaniser, or the makers, they are soon disposed of by rubbing French chalk well into the canvas and painting the outside with a tyre preservative. They should then be kept in a cool, dark, dry place till wanted. If the canvas has any weak places it will pay to have the cover relined, and when considering this point it is as well to remember that it will very materially decrease the chance of punctures. Many thorns and nails will pierce a single double ply of fabric which have not length or strength enough to penetrate the tube when the cover is provided with a treble lining of canvas. Make a point, however, of seeing that the new lining is brought right up to the edges of the old canvas, and not cut off just by the beaded edges, as the latter is likely to cause trouble.

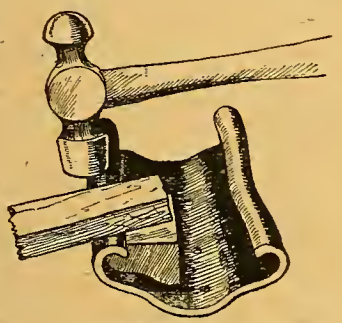

Fig. 3.—Hammering dents out of the rim. A piece of metal is placed inside the beaded edge and a piece of wood on the top to prevent damage by the hammer blows.

In the case of the inner tubes, I strongly advise vulcanising all patches. Jointed tubes also require a little attention at the ends occasionally, such as solutioning down the internal rings and external flap. When replacing the air tubes in the covers and when packing up the spare tube be lavish with the French chalk.

Wheels.

The rims should be carefully cleaned of all rust, specially along the beads, where it may cause serious trouble. Any dents should be hammered out, using a piece of hard wood between the hammer and the rim, so as not to injure it, and placing a piece of metal in the bead to prevent it closing. Truing up, if required, may be done at home by clamping the spindle firmly in a vice, protecting the thread with lead or leather, rotate the wheel slowly, holding a piece of chalk against first one edge of the rim and then the other, advancing it just far enough to leave a mark on that part which projects most. Now with a nipple key or spanner tighten up the spokes gradually by giving a quarter turn at a time to each nipple on the opposite side of the rim to these marks till they have merged into the general line of the rim. It may be necessary in the course of this operation to slacken the spokes on the same side as the chalk marks in order to get the rim to set over. In any case, when the rim is true all spokes should be tensioned to give as nearly as possible the same note when struck, and the spoke ends which protrude from the nipples must be filed flush with the nipple heads.

The spindles should be removed and the cups, cones, and balls examined for signs of undue wear or fracture and the faulty parts replaced. Most motor cyclists have been troubled at some time or other with a ball bearing which is either so slack as to rattle or if it be adjusted tighter the wheel will not swing freely. This is due to a worn cup or cone, which should be replaced. For the all-weather rider the rim, spokes, and hub should be enamelled, as this will save a lot of time in cleaning. When replacing the spindle unscrew the lubricator from the hub and fill up the barrel with liquefied vaseline or thick cylinder oil, and the bearing will then be well lubricated for the best part of the season, and require no further attention. The treatment of the bearings of bottom bracket (if pedalling gear be fitted) and pedal bearings is similar to the above except that the spindles for the latter or the cranks may require straightening.

Belts and Chains.

Leather belts should be well scraped, or brushed, with a file card on the sides, and dressed with Collan oil. Any rivets which may have pulled through should be replaced, putting a washer under the head of the rivet large enough to prevent a recurrence. Only chain belts and one or two others like the Watawata should be coiled up tightly when carried as a spare, as the small coils stretch and weaken the canvas or solid leather, as the case may be. Rubber and canvas belts should be freed from all dust and mud, and any exposed portion of the canvas, if not gone too far, may be given two or three coatings of rubber solution by way of waterproofing. This may also be applied to the cut ends of the belt, and so, by keeping the wet out, lessen the chance of rotting the canvas and the fasteners pulling through. Be sure that your spare fasteners are in working order, and always carry two spares. If you desire to be really self-reliant, carry a complete spare belt ready cut and stretched to the correct length, and fitted with a fastener.

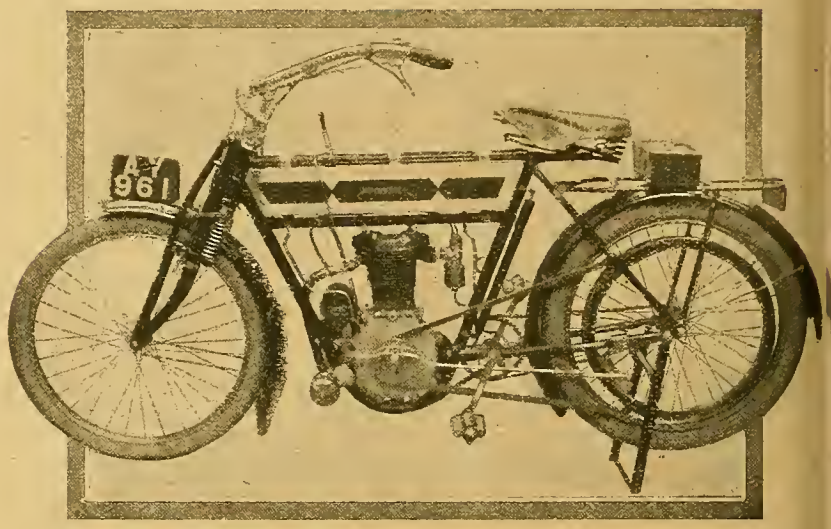
As regards chains, both for driving the back wheel and the magneto, there is no better method of cleaning them than washing them first in paraffin, hanging them up to drain, then, after previously heating the chain, immerse it for fifteen minutes or so in melted Russian tallow. The tallow should then be allowed to cool sufficiently to show signs of thickening, when the chain may be removed.

If it be taken out before the tallow commences to solidify the hot grease will drain out of the joints.

(To be continued.)

THE NEW CLYDE MOTOR BICYCLE.

THE Clyde motor bicycle for 1910 is a well designed machine of neat appearance and on well-tried lines. The model illustrated is fitted with a 3½ h.p. single-cylinder White and Poppe engine, 85 by 85 mm. bore and stroke, but a J.A.P. engine of the same dimensions may be obtained instead if ordered. A free engine clutch and Phelon & Moore two-speed gear are also optional fitments. It will be noticed that the saddle is carried on an extension of the top tube to give a low riding position. Other standard features of the Clyde are: Special design of loop frame, band and luggage carrier, footrests, Druid spring forks, and B. and B. carburetter. The brakes consist of a front rim hand-applied brake, and a belt rim brake operated by a lever on the footrest. The magneto is neatly situated in a screened position in front of the cylinder. It may not be generally known that the makers of the Clyde—Messrs. G. H. Wait and Co., Leicester—were one of the pioneers of magneto ignition for motor cycles.



The 1910 model Clyde, with the engine carried in a loop frame, presents a very taking appearance.

A FAMILY SIDECAR.

MR. A. POWELL, of West Bridgford, Nottingham, sends us photographs and particulars of his new sidecar combination which he has fitted up himself, and which no doubt will be scrutinised with interest. The machine is undoubtedly a most pretentious one—probably too pretentious—for it is demanding a little too much for any motor bicycle and sidecar to carry five.

The specification of the machine is as follows: 8 h.p. J.A.P. twin-cylinder engine with m.o.i.v. J.A.P. handle-bar controlled carburetter and automatic lubricator; Chater-Lea No. 6 frame; J.A.P. free engine clutch controlled from handle-bar; handle starting; footboards; Michelin 26in. by 2½in. extra strong tyres; 1in. Watawata belt; dual ignition by Bosch magneto and Fuller's coil and accumulator; and Cowey speedometer.

The sidecar is a flexible pattern Montgomery, fitted with special attachment at rear to accommodate two children. There is a luggage box under sidecar seat, which is useful for touring purposes.

Both the bicycle and sidecar are enamelled grey.

A "family" sidecar owned by Mr. W. Powell, of West Bridgford, and described above.

We are repeatedly asked by riders of both magneto and battery ignited machines how they can prevent explosions in the silencer when the exhaust valve is lifted. Any motor cycle engine which is subject to it can be cured by fitting a handle-bar switch. A very neat type of switch for handle-bars has been submitted to us by the Bowen and Odery Manufacturing Co., 62 New Cross Street, S.E. It can be fitted in such a position that the switch lever can be placed in the "on" or "off" position with a touch of the finger

An Owner's Experiences with a Scott Motor Bicycle.

NOT having read so far any description of a private owner's experiences with the Scott two-stroke motor bicycle, possibly a short account may be of interest to those who contemplate investing in one of these machines. I bought mine in November last, and though I have only ridden a few hundred miles, the fact that this distance has been over Irish roads during the winter months makes it equal to double the distance on good roads in summer time.

For ease of starting, one must go far to find an easier. A little petrol is injected through the spring nipples on the side of each cylinder, at any rate in cold weather, and then, while seated on the saddle, a smart push with the instep of the right foot on the starting crank, which is permanently attached to the back hub, and the engine starts. You close the handle-bar controlled throttle a little when the engine is running well, a matter of a few seconds. Then, with your left foot on the ground, press the low gear pedal gently with the right heel, and off you go smoothly without jar. By adjustment of throttle and extra air lever you can run at about eight miles an hour on the low gear, and by closing the extra air, and cutting the magneto in and out with the handle-bar lever, you can crawl behind cattle or traffic, as I frequently have to do on market days.

Changing Gear.

When the rider is ready to go faster, the high gear pedal is pressed forwards and downwards, as smartly as you like, and the hum, which on the low gear sounds loud and of a high tone, changes to a low quiet note. In fact, when the mixture is correct, the rider can really only hear the swish of the chains.

If you want to run up to a point and stop, you cut out your magneto, put your gear pedal into the horizontal free engine position, and apply your handle-bar brake. If you want to pull up short, you go through the same process, but put on the shoe brake on the back sprocket wheel, which is operated by a pedal placed conveniently near the left heel. This will pull the machine up and stop the engine, but the jar must necessarily be a strain on the engine, so unless there is urgent need it is always better before stopping to put the gear pedal in the free position.

The control becomes quite automatic in a very short time, though I suffered one fall when new to the machine, through forgetting the heel pedal, having been used to the Triumph and Bat toe pedals.

The spring forks are excellent, but the rollers must be kept oiled, or they squeak. There is practically no engine vibration, as the explosions follow each other so rapidly as to be indistinguishable, merely merging into a continuous hum.

The water cooling has so far given me no trouble, and I see no reason why it should, except that the indiarubber union piping will want renewing periodically. The gauzes over the transfer ports want looking to occasionally, and, if fouled, cleaning with petrol and replacing. It is as well to carry a few spare pieces of gauze of the correct size, as the cost is very small. Up to the present the sparking plugs have shown no signs of sooting up.

It is a wonderfully clean machine to ride, as the undershield keeps all dirt off, and the tank, being slanted below the saddle, keeps any oil from the gear chains from flying about.

The lubricating oil is carried in the two main down tubes and injected by a hand pump placed near to the junction of seat and down tubes. This is no trouble when the oil is warmed and thinned by the heat of the engine, but when oil is cold, as in frosty weather, it is a hard job. I wish the makers could see their way clear so to make the pump that the handle pulled up towards the rider instead of away from him, as it does now.

Accessibility.

It is a great boon to be able to see the actual level of the oil in either crank case in about fifteen seconds by simply undoing a wing nut, and also to be able to verify that one's oil pump is working, as with the crank case open one can watch the level of the oil rise when the pump is operated. The carburetter seems most efficient, and the ease with which the jet can be removed, cleaned, or changed is very nice. To remove the carburetter entirely is more of an operation, but when one has done it once it becomes quite an easy matter.

The tank holds plenty of petrol for at least 100 miles, and is fitted with a large filling orifice and strainer. The magneto is excellently placed out of harm's way behind the tank, and is driven by a chain. I suppose that in time the chain will stretch enough to make a readjustment of the ignition necessary, but I have not required to meddle with it so far, and when I do the makers' instructions are so clear that I foresee no difficulty.

One or Two Suggested Improvements.

No machine is perfect yet, and as a non-expert amateur, if I were asked to improve on the Scott, I should ask for a more easily worked oil pump, or, better still, an automatic lubricator, extra air lever to be handle-bar controlled, main driving chain to be protected in some way, and a better catch for the stand.

Speaking generally, the Scott is beautifully made:

An Owner's Experiences with a Scott Motor Bicycle.—

every nut fits perfectly, and where necessary is assisted by a spring washer; so nothing seems to want to come adrift, and the tools provided in the tool case fit all nuts, etc., quite well. The tyres are the best money can buy. I have ridden now a great many miles over greasy Dublin tramlines, and only once had a sign of a side-slip. The machine is a pleasure to ride and own, and I wish I had the time to ride in the Quarterly and End-to-end Trials; nevertheless, I hope to see the Scott carrying some riders well to the fore this year. Needless to say, I have no connection with the Scott firm, but I am quite sure the makers have got a good thing, and have gone the right way about making it, viz., by incorporating the very highest class of workmanship and materials. H. G. K.

The Law and its Relation to Motor Car and Motor Cycle Owners.

A PAPER with the above title was read before the members of the Middlesbrough and District M.C.C. on the 2nd inst. by Mr. Alex Lauriston, honorary legal adviser to the club, who has kindly provided us with a copy and given us permission to publish whatever we consider will be helpful and of interest to motor cyclists.

As Mr. Lauriston pointed out, whatever appears in the paper with reference to motor cars applies equally to motor cycles, except where the contrary intention is mentioned.

The first portion of the paper dealt with the meaning of the various Acts of Parliament which apply to motors, and gave the limits of speed allowed. We regret we have not space for more than a summary of the various points which particularly appeal to motor cyclists. These are given below:

A person cannot be prosecuted for exceeding the speed limit unless he is warned of the intended prosecution at the time the offence is committed, or notice of the intended prosecution is sent to him or the owner of the car as entered on the register within such time after the offence is committed not exceeding twenty-one days as the court thinks reasonable. It has been held with regard to the former part of the above section that if a constable stops a driver and informs him that he thinks he is exceeding the speed limit, but if after he has compared his time with another constable three miles away and he finds he has not exceeded such limit he would hear nothing further about it, this is sufficient warning for the purpose of the section.

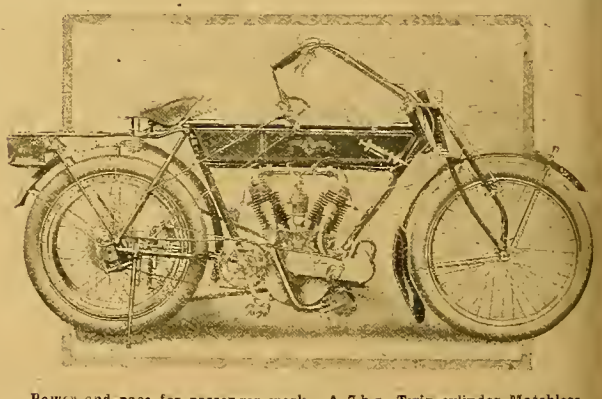
The penalty for offences under this section is for a first offence a fine not exceeding £10, second offence not exceeding £20, and subsequent offences not exceeding £30. Any person upon whom a fine exceeding 20s. is inflicted (Section II.) may appeal to quarter sessions against the conviction, but it has been held that where a person was fined 20s. and 18s. costs the section did not apply, and there was no right of appeal (Rex V. Novis, 1905).

Giving Warning of Police Traps.

Should anyone know of a police trap in his district he would have been quite at liberty twelve months ago to warn the unwary motorist of the same, as the Court has decided that by so doing a person did not obstruct the police in the pursuance of their duties, but a phrase from the lips of Lord Chief Justice Alverstone, with which Justice Darling entirely concurred, and which was pregnant with meaning and suggestiveness, is worthy of note, viz., "That the obstruction of a constable in the execution of his duty need not necessarily be physical obstruction." This decision has now been over-ruled, however, by a very recent case (Betts *v.* Stevens), and it has been held that a person can be so convicted. However, Lord Alverstone also stated that where one motorist gave another a friendly tip there was no breach of the law. He also said that in the previous case there was no evidence that there was driving beyond the limit, and that as the result of the warning the drivers pulled up. Before leaving the question of speed there is another section of the 1903 Act which is of the highest importance, and one that the motorist should be acquainted with, and yet the language of which is so general that absolutely no definite rule can be laid down to keep the motorist out of the clutches of the law but an appeal to his own commonsense. It enacts "That any person driving a motor car on a public highway recklessly or negligently, or at a speed or in a manner dangerous to the public having regard to all the circumstances of the case, including the nature, condition, and size of the highway, and to the amount of the traffic which actually is at the time or which might reasonably be expected to be on the highway, that person shall be guilty of an offence under the Act."

Skidding not Negligence.

It has also been held that where your machine skids and there is no negligence on your part, and as the result of such skidding some other person is injured or suffers damage, you are subjected to no liability. In my experience I do not think I have come across any particular offence which it is more difficult to defend a person against than offences against the speed limit or reckless or dangerous driving. That arises from the fact that the alleged offence may be committed in either case, and you are are not stopped



Power and pace for passenger work. A 7 h.p. Twin-cylinder Matchless-J.A.P. with two-speed hub gear, the engine being started by the pedals with the back wheel resting on the ground.

while so doing, consequently by the time you are charged you are unable to get rebutting evidence to resist that of the prosecution, and there is only *(in the majority of cases and particularly in the case of a motor cyclist)* your own uncorroborated word. Where a person has been guilty of either of the above offences a prosecution under one section of the Act is a bar to a prosecution under the other section. That is, if they prosecute you for going over twenty miles per hour they can't take a second prosecution upon the same facts and charge you with reckless driving and *vice versa*. Just in passing I should like you to take particular notice of a recent decision of great practical importance (Burton *v.* Nicholson) in which it was held that a motor passing a tramcar going in the same direction must pass on the right or offside, just in the same manner as you would pass any other carriage on the road. The practical importance of this case has now been done away with by the rescinding of Art. IV. (3 and 4) of the Motor Car (Use and Construction) Order, 1904, and now, although the ordinary rules of the road must be observed, there is no hard and fast line drawn, if by such observance it would endanger any person (Finegan *v.* L. and N.W.R. Co. and Hartley *v.* Chadwick).

In case of all offences under the Act (except the first and second offence which consists merely of exceeding the speed limit) the Court must endorse the licence, but it is discretionary whether or not they shall suspend the operation of it or declare the person unfit to have one. In only one

The Law, and its Relation to Motor Car & Motor Cycle Owners.—

case under the Act of 1903 has a police constable power to arrest a motorist, and that is when he drives to the public danger in the sight of a police constable and refuses to give his name and address or produce his licence on demand. Note the word "or" is mentioned in the section, so that although you give your name and address and do not produce your licence you can be arrested. It is the duty of every motorist to stop if an accident occur to any person whether on foot, horseback, or in a vehicle, or to any horse or vehicle in charge of any person owing to the presence of a motor car on the road. When you do stop you must give your name and address and number if requested, but not otherwise. This section is exceedingly narrowly drawn, but of course we must not grumble at that, as the narrower the section the more limited and restricted is the liability of the motorist. If there is an accident to a horse, stop; if to a dog, cow, or any other animal you are not bound to stop.

Production of Licence on Demand.

Any police constable can stop a driver of a motor and ask him to produce his licence, and if he fail to do so he is guilty of an offence and liable to a fine not exceeding £5; but if he fail to do so the constable cannot arrest him unless he charges him with riding to the public danger and alleges he saw him do so. It makes no difference whatever if the police constable knew that the person had a licence, the offence lying in the fact of non-production and not in the fact of not having one I know one or two motorists who are always looking the other way when they see the hand of a police constable go up, as they think that the logical result of dismounting would probably bring about a state of things which would be anything but pleasant. This sentence may appear rather of a paradoxical character when I speak about looking the other way and yet seeing the police constable's hand, but I have no doubt the meaning is apparent to all. The Act does not state you must dismount when the hand of an officer of the law goes up, nor does it make it an offence or attach any penalty for the non-dismounting, but simply states that "Your licence must be produced on demand of a P.C.," and I can't for one moment conceive if we give the greatest laxity possible to statute construction that a motion to stop could be constructed as a demand for a licence. However, you must stop if you see the hand, as the weak part of the Act has been strengthened by the Motor Car Order 1903, which declares this. You must also stop if a person with a horse asks you to do so. Suspension or endorsement of licence gives no power whatever to the person aggrieved to appeal against the same, but disqualification to hold a licence gives a right of appeal [Sec. IV. (4)]. This is without doubt a section which might possibly bring about a tremendous amount of hardship to the motorist, seeing that the Act does not limit the time during which an order for suspension may last.

Audible and Sufficient Warning.

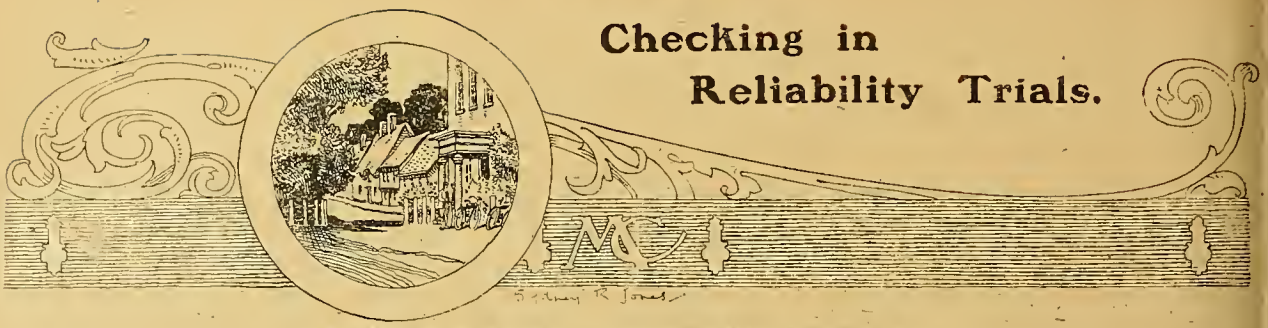
With regard to the question of carrying a bell or other instrument capable of giving audible and sufficient warning of the approach or position of the machine, lighting up between one hour after sunset and one hour before sunrise, and also having two brakes. I should like to draw your attention to two decided cases dealing with the above matters. The first is that sunset and sunrise are to be considered at the place at which the motorist is actually at when the alleged offence is committed, and not as to time of sunrise and sunset at Greenwich. The other decision is where a person was charged with not having two independent brakes on the car he was driving. The car had one brake on the back wheels, and the only other brake was that obtained by using the engine so as to lock the wheels. The magistrates found that, although the engine could be used as a brake, it was not an independent brake and convicted the offender. The magistrates' decision was upheld upon appeal.

WATER COOLING ON MOTOR BICYCLE ENGINES.

I WAS very much interested in the article on water cooling in *The Motor Cycle* of January 3rd, having ridden a water-cooled motor cycle myself for the last four and a half years. I bought my first machine (a 2 h.p. Quadrant) in 1902. I tried various other makes during the two years following. In the autumn of 1904 I examined a two-cylinder air-cooled machine, the Princips. I also had some correspondence with regard to the Hamilton, but found it impossible to get delivery of either under a couple of months, so finally invested in a twin-cylinder water-cooled Iris engine and a brass water tank provided with two small white metal radiators on either side.

I had previously read an account of this engine in *The Motor Cycle*. I examined the complete machine both at the show and at Brixton. I did not take a fancy to the frame, so I had the engine, etc., fitted to a big Chater Lea dropped frame. The cylinder dimensions were 70 mm. by 100 mm., and there was any amount of power. Later on I discarded this engine in favour of a water-cooled single-cylinder White and Poppe. This was a beautifully finished piece of work, but rather small according to my idea (80 mm. by 85 mm.), so I sold it and bought a Star with water-cooled single-cylinder Stevens engine (90 mm. by 96 mm.) This machine, which I still ride, develops immense power, and will take me anywhere. The engine has never been taken down, and the original valves and springs are still in use. The former have been ground in twice. My mileage for the four and a half years is about 8,000, chiefly made up of short journeys in hilly country. The water tank holds about a gallon, and I have no radiator, but eight or ten horizontal tubes, open at both ends, run right through the tank. I use this machine in the working of a scattered country medical practice, and find the cooling sufficient; but if a long journey is undertaken, the tank requires refilling about every fifteen miles. This is with a gear of 4½ to 1 and a fairly efficient carburetter. The machine runs about sixty to seventy miles per gallon of petrol, and my weight is fourteen stones, that of the machine being 168 lbs.

My experience with the twin-cylinder Iris was similar to the above, though the tank on that machine was somewhat larger. I used the same tank with the White and Poppe single-cylinder engine, and found, of course, that the water lasted much longer. My experience with tricars of three and four years ago fitted with the thermo-syphon system was that the water boiled in a few miles. On my 12 h.p. Swift car I have toured for a couple of weeks in Devonshire, and lost barely a pint of water; yet the whole cistern only holds about three and a half gallons. In my opinion, a water pump, radiator, and fan make the whole difference. The water pipes on my motor cycle are not large, and, of course, big waterways and large radiators would make a difference, but I doubt if water cooling on motor bicycles is suitable for touring and long distance riding. I have heard excellent accounts of the Scott, and hope to try one before long, for if only rapid evaporation of the water can be prevented the water-cooled machine presents many advantages, amongst which are no loss of power from overheating and greatly prolonged "life" for the engine, especially its valves and springs.—M.R.C.S.



Checking in Reliability Trials.

By FELIX SCRIVEN, Trials Hon. Sec. Bradford M.C.C.

WITH reference to "Ixion's" remarks in the issue of January 17th on the subject of checking in reliability trials, it may not be generally known that the system adopted by the Bradford Motor Cycle Club has been most successful, and is one that should be carefully considered by committees who have the arrangements in hand for our big trials.

In the first place, a checking committee is formed from a number of riders who are willing to undertake the duties of checkers, and a goodly number of checking stations are decided on, the chairman of committee or some other experienced rider generally suggesting the likeliest points at which they should be situated.

I must first point out that in the Bradford Club the trials committee depends almost entirely on surprise checks, only a few known checks being stated on the route card.

Trials are held primarily for proving or disproving the reliability of rider and machine, and there is no surer way of detecting unreliability than by checking a rider at an unexpected point.

In all the Bradford Club's trials it is stated on the route card that "a check may be taken at any mile post *en route*," and, furthermore, in all competitions (except those reserved for novices) a stringent rule is enforced. "No adjustments whatever allowed in control": thus the only thing which can be done to a rider's machine in control is the replenishment of petrol, oil, and carbide.

Now as to the equipment of riders and checkers, both are, of course, provided with route cards which show the scheduled time of the first man at various points *en route*, and which also give total and intermediate distances.

The Essence of the Regulations.

The rider is also provided with a glass fronted watch case which is capable of being sealed, and which may be put in the pocket, clipped to the handle-bar, or can be attached to any part of the machine or the rider's anatomy which may happen to be convenient. The rider turns up at the start and sets or gets his watch set to the official time, and stows it snugly away in the watch case amongst plenty of cotton wool, placing the face of the watch so that it is easily visible through the glass front of the case, which is sealed. Then at the word go he rides off, keeping as near as ever he knows how to an average of twenty miles per hour.

At a point, say, exactly five miles on his journey, he may quite unexpectedly encounter a checker. Of course, the competitor should arrive at this point fifteen minutes after he started, and the checker promptly takes the actual time of the rider's arrival from the sealed watch, which the rider must, if required, immediately on coming to a standstill submit for observation to the checker.

I can hear someone say, "What about filling in checkers' cards?" The necessity for this is done away with.

The checker has been provided with a checkers' duplicate book, with its pages divided into leaflets which can be detached by tearing round the perforated edges. On each leaflet, which is numbered like a cheque, blank spaces are provided, which the checker must have previously filled in as far as possible.

The leaflets read as follows:

Check taken at ..... (the number of) Miles to ..... (the name of place) and ..... (the number of) Miles from ..... (the name of place). Competitor's number ..... Competitor's time ..... Checker's signature .....

Now it will be seen that every blank space can be filled in beforehand with the exception of "competitor's time," so that the sole business of the checker on the arrival of a competitor is to read the time from the sealed watch and put it down on the leaflet, tear the leaflet out, and hand it to the competitor, who by accepting it acknowledges the checker's figures to be correct. Should the competitor's watch stop he must declare it, and take the checker's time in the ordinary way, and he can at the first opportunity replace the faulty watch and get his watch case resealed by an official.

Results Easily Calculated.

At the end of a competition any competitor can reckon up for himself the number of points lost, by simply referring to the leaflets torn from the book and of which the checker holds a duplicate, and see to what extent he varied from scheduled time at the various checking points on the road, so that he is bound to be absolutely satisfied with the declared result of the competition. At the end of the competition it is the duty of the checker taking the finishing times to see that all seals on the rider's watch cases are intact.

After performing their duties checkers must immediately hand in to the trials secretary or other official the counterfoil book of duplicate signed pages. Should a competitor dismount in sight of a checker his time is immediately taken.

The trials committee now examine the books and calculate from the duplicates the points lost by each

Checking in Reliability Trials.—

individual. There is also a recording slip to each page of the checker's book, on which it is stated by the checker in what competition and at what point his check has been taken, so that in the checker's book there is a complete and permanent record of all checking times taken in competitions and of the numbers appearing on each leaflet of the page.

This system may sound a shade complicated, but in practice it has proved no small success, and I see no reason why it should not be applied to any number of competitors. We always start competitors at two minutes intervals, and we find that the checkers have ample time to do their work.

I have not had to deal with a reliability trial in which there has been a field of sixty competitors, but have assisted in the organisation of trials covering a distance of about 420 miles with a field of thirty-five entrants.

There seems to be a deal of "scrapping" to obtain petrol and to get checks signed in the competitions to which "Ixion" refers, and for our system of checking this would never do, so as a perfectly natural sequence we schedule a ten to fifteen minutes stop (strictly in control) at any point where we consider a rider's supply of petrol will be likely to be getting low, and we endeavour to fix these points not at an ironmonger's shop, but at a garage or hotel where an efficient staff, supervised perhaps by one of our own officials, does the necessary replenishing of tanks.

In our twenty-four hours run (for example, Bradford to Edinburgh and back, a distance of over 400 miles and considerably harder than London to Edinburgh, as we get a double dose of the hilly half and very little of the flat), in order to qualify for a gold medal, one must at no point of the journey be found more than three minutes ahead or ten minutes behind one's scheduled time.

Suggestions for the Six Days' Trials.

For the six days' trial I do not suggest so drastic a regulation as this, but I would do everything to encourage steady and regular riding, and disqualify for premier awards any rider who was unfortunate or unskilful enough to be, say, twenty minutes behind and ten minutes ahead of his scheduled time at any point during the 1,000 miles of the trial, neither would I award him premier honours had he lost more than a predetermined aggregate number of marks.

I would suggest that threequarters of an hour every morning should be amply sufficient time for adjustments and very minor repairs. That there is always a chance of a competitor taking the wrong road I agree, but if the route card be properly compiled and give sufficient directions for doubtful turnings, together with a certain number of special signs or guides placed at the road side, the risk of a careful competitor spoiling his chance by losing more than twenty marks at one check would only be a small one.

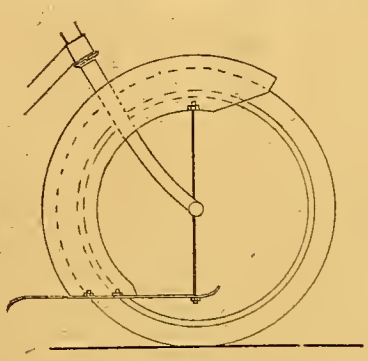
"Monotonous," you say. That I grant, but it is the monotonous reliability of our present day mounts which makes it so, and there is no reason why in such trials as the six days, riders should not be despatched in pairs at two or three minute intervals. Also the six days' trial competitors are lucky enough to have their competition livened up by two or three hill-climbs, and I feel convinced that events such as trials based on the above lines are the only ones which have a future before them, and which will discover to any appreciable extent the weak points of machines. For instance, where would our friend Mr. B. H. Davies have been after one or two of his lengthy stops owing to carburetter troubles?

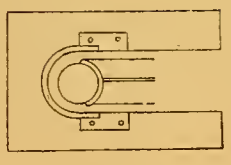
Organisers and competitors must unflinchingly face the fact that trials, to be of any real worth, can no longer be regarded in the light of a pleasant ride round the country by a number of most amiable enthusiasts.

As a matter of fact, I believe that the six days' trials are looked down upon as child's play by some of our keenest North of England riders, and after having experienced the rigours of many long trials on the above lines, and read the criticisms of many contributors and correspondents in *The Motor Cycle*, I am inclined to think that they are justified.

A MUDGUARDING DEVICE.

Mr. Henry A. Ellis, M.A., M.S.A., 10, Fisher Street, Swansea, has provisionally patented a mudguard for motor cycles which comprises a flap or shield suspended about the wheel and near to the ground. The ordinary mudguard effectually stops the mud which is thrown up by centrifugal force, but does not ward off mud splashed outwards by the contact of the wheel with the muddy surface. The shield consists of a wide strip of material, bifurcated to admit the wheel, and curled upwards at the front and downwards at the rear. The shield is bolted, riveted, or fastened to the existing type of mudguards and suspended or otherwise fixed to the hub spindle. This does not appear to differ greatly from a similar device we have seen in use on pedal cycles.





The patentee says this shield, if used in conjunction with a wide flap guard, as shown on the drawing, will be found effectually to prevent the rider being splashed with mud, whatever the state of the roads.

The Millennium Auto-grip spanner has been introduced to provide quick and accurate adjustment without injury to the nut or hands of the operator. The action is obtained by means of a short toothed rack in the loose jaw actuated by a toothed quadrant on a pivoted handle. This tool, which is manufactured by Lake and Elliot, Braintree, Essex, will take any size nut up to $\frac{15}{16}$in. across the flats, and is guaranteed not to slip or round the corners of the nut.

Three New Clubs projected.

New motor cycle clubs are contemplated for Doncaster and district, Radnorshire, and Burnley.

The Forthcoming Manchester Motor Show.

Only motor cycles and cars will be exhibited at the Manchester Show, which opens on Friday next. Last week we inadvertently mentioned that cycles would be among the exhibits.

The First Aeroplane Catalogue.

What is believed to be the first British aeroplane catalogue in existence has just come into our hands. It has been issued by the Humber Co. The catalogue is an interesting production, and, we should say, should prove in the future quite an historical document.

The Quarterly Trials Results.

The decision of the A.C.U. Competitions Committee not to award marks for general excellence of design has made the positions of the leaders still closer. Only one mark separates the first eight competitors in the running for the silver cup.

Imports and Exports of Motor Cycles.

Both imports and exports of motor cycles during January were greatly in excess of the figures for the same month of last year. The number of complete machines of foreign manufacture imported during January was :

1908.	1909.	1910.
217	24	120
Value—		
£6,124	£629	£3,676
Parts thereof—		
£611	£2,184	£3,888
£6,735	£2,813	£7,564

The exports of British machines during last month compared with the two previous years were :

1908.	1909.	1910.
68	82	238
Value—		
£2,202	£2,461	£8,702
Parts thereof—		
£2,601	£2,043	£2,283
£4,803	£4,504	£10,985

Re-exports.

Re-exports of foreign motor cycles and parts during January were valued at £524, as against £1,188 in the corresponding month of last year, and £721 in January, 1908.

SPECIAL FEATURES

HOW TO OVERHAUL A MOTOR CYCLE.

CHECKING IN RELIABILITY TRIALS.

SPRING FORK DESIGN.

Timing of the Magneto Spark.

Lecturing on "Magnetos" before members of the Bolton and District M.C.C. the other evening, Mr. A. E. Bennett said: "We have all come to the conclusion that the saving effected by a fixed point of ignition provides a great saving in the life of an engine, and produces a better running effect than is possible otherwise."

A Procedure that might be Copied.

A meeting of secretaries of Scottish motor cycle clubs was held at the Carlton Hotel, Edinburgh, on the 5th inst., to arrange the fixture lists for the year and prevent clashing of dates. Representatives from the Edinburgh, Glasgow, Leith, Perth, Ayr, Dundee, and other clubs were present, and it was recognised that an arrangement of this kind will do much to add to the interest of Scottish events during 1910.

Records.

At a recent meeting of the Committee of the A.C.U. the following Brooklands class record was passed: One kilometre, flying start—W. E. Cook, 20 h.p. N.L.G., 26.553 secs., 84.247 miles per hour, June 6th, 1909.

The Early Entries for the T.T. Race.

It is quite remarkable that so large a number of entries have been received for the Tourist Trophy Race when it is taken into consideration that the latest regulations have not yet been issued. Now that the Highways Board of the Isle of Man has unanimously agreed to sanction the race, and the Governor has given his consent, there should be nothing to prevent the success of the competition.

FUTURE EVENTS.

Feb. 18-26—Manchester Motor Cycle Show, City Exhibition Hall, Deansgate.
Mar. 12—M.C.C. Opening Run.
,, 16—(Wed.) British Motor Cycle Racing Club Meeting at Brooklands
,, 25—General Meeting of Northern Motor Cycle Clubs at Richmond, Yorks.
,, 25—M.C.C. Easter Tour. Jarrott Cup Competition.
,, 28—Brooklands A.R.C. Easter Meeting.
,, 30 to April 2—Exhibition of Motor Cycles, at Leicester, Association Hall.
Apl. 13—(Wed.) B.M.C.R.C. Meeting at Brooklands.
,, 20—A.C.U. Second Quarterly Trial.
,, 27-28—Brooklands A.R.C. Meetings.
,, 30—M.C.C. Members' Hill-climb.
May 4—B.M.C.R.C. Meeting at Brooklands.
,, 13, 14, and 16 (Whitsun)—M.C.C. London-Edinburgh and London-Edinburgh and Back Runs.
,, 26 (Thursday)—International Motor Cycle T.T. Race in the Isle of Man.
,, 28—A.C.U. Open Hill-climb.

Quarterly Trial.

The judges' report of the A.C.U first Quarterly Trial of 1910 appears i this week's Supplement.

A.C.U. Annual General Meeting.

The annual general meeting of th A.C.U. will be held at 112, Piccadilly on Saturday, 19th March, at 5.30 p.m The annual general meeting of privat members will be held also at 112 Piccadilly, on March 2nd, at 7 p.m.

Permit Granted.

The A.C.U. has granted a specia permit to the Herts County A.C (motor cycle section), the North-wes London, and the Harrogate and Dis trict M.C.C. to run an inter-team com petition, starting early on Good Frida morning from London to Harrogat and back.

Tyres on Lightweights.

Mr. H. A. Cooper writes with refer ence to a paragraph in last week's issu referring to tyres on lightweights i the Quarterly Trials: "It is not fact that all lightweights qualifyin for a non-stop run were shod with on make of tyre. I rode Palmer Cords which gave me every satisfaction, an were as steady as a rock on any sur face, as well as on the tramlines righ through London."

The Cause of Two Falls.

Mr. E. F. A. Hay, of Oxford, write apologising to Messrs. Silver an Bowen for accidentally causing them to fall off their machines during th Quarterly Trial on the 29th ult. I appears that Mr. Hay, who was a non competitor was riding with the trial men when he suffered a skid, bringin down the above-mentioned competitor who were following close behind.

Motor Cycle Repairers Officially Appointed by the R.A.C.

A short time ago a paragraph ap peared in these pages to the effect tha repairers who were desirous of apply ing for the Royal Automobile Clu motor cycle official repairship shoul make their applications without delay The result of this notice was to caus over ninety firms within a week to sen in their names to the R.A.C. Tourin Department. Others should lose n time in following their example. On of our correspondents suggests tha repairers who undertake to supply les than two gallons of petrol on deman should have an asterisk placed agains their names. A list of the appointe repairers may be obtained on applyin to the secretary of the Auto Cycl Union, 18, Down Street, Piccadilly, o to the R.A.C. Touring Department 108, Piccadilly, W.

OCCASIONAL COMMENTS

BY "IXION"

Amulree and the Six Days.

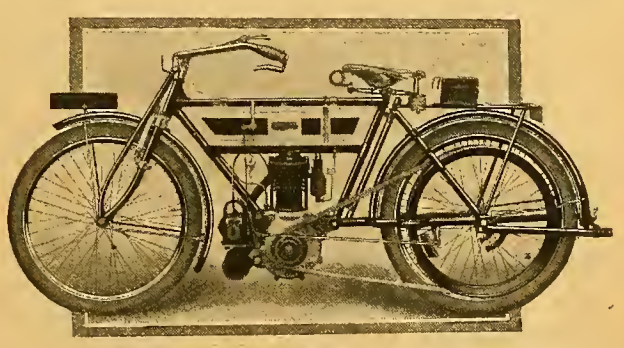
I now hear officially that the A.C.U. trials are leaving the southern or Sma' Glen side of Amulree to the Scottish Trials, and that the English entry must face it from the northern or Kenmore side. As I stated in a recent issue, I doubted if this was practicable for motor cyclists, as I have a vivid recollection of sliding down sledgewise on a car with my rear wheels locked, while the surface was execrable to a degree. I am told, however, that Mr. Bischoff has climbed it comfortably enough on a T.T. single-cylinder, and certainly the competitors are less likely to be climbing against a gale if they face it from the north. I hope the surface will be in decent order, but, in any case, I fancy no hill in any previous A.C.U. trial will have been so severe a trial for the competitors as Amulree will be this summer. Intending entrants, open out your adjustable pulleys, and envy the men with the two-speed gears. The A.C.U. is working on the right lines when it incorporates hills worthy the name in its reliability trials. A chorus of appreciation rises from riders in remote country fastnesses who know what the machines which win hill-climbs will not do when they work week in and week out, daily facing hills with single figure graded corners which are never dry or smooth.

Overgearing

Quite a number of enquiries annually received at this office show that overgearing is a very frequent reason for dissatisfaction with a motor cycle which would give excellent service if its gear were reduced a trifle. When all is said and done, the factories in which British motor cycles are constructed are chiefly situated in the Midlands and the Metropolitan district, and the only road test which complete machines receive before despatch to a customer is confined, at any rate, to a fifty-mile radius from the factory. This radius usually provides a decent test hill—often some little back lane with a short patch of single figure gradient. The machine will take this climb with a flying start when it is new, and so either a fixed pulley, supplying this gear, is standardised, or else the adjustable pulley is screwed up to this ratio. But quite a decent percentage of riders live in the hilly counties of the North and West or in one of those hilly tracts of little known country lying between our great highways, from which real climbing has been skilfully eliminated. Add to this the fact that few riders are expert enough to maintain an engine in "factory tune," and it is easy to see why some riders complain that their mounts are inefficient on hills. There are very few roads in England and Scotland which I have not traversed, and there are enormous tracts of country in which I would not regularly ride a standard geared machine, especially in spring, autumn, and winter. The first thing to do when a well-tuned machine evinces a lack of certainty in hill-climbing is to lower the gear. Some riders employ this expedient, only to discover that their engine promptly runs hot. If so, the use of the lower gear should still be possible if either the amount of lubricating oil is slightly increased or the carburetter readjusted. The latter has the more pronounced effect. I especially remember a visit one holiday to a very hilly and little known corner of England, where the pride of my eyes, a very excellent 3½ h.p., disgraced me on many hills. I met three or four local riders at an inn one day for tea, and found they all made light of the hills which had proved my Waterloo, although they were using much smaller engines. I was just resolving to go back home and learn how to tune an engine again, when I found their gears averaged about 6 to 1, whereas mine was 4¼!

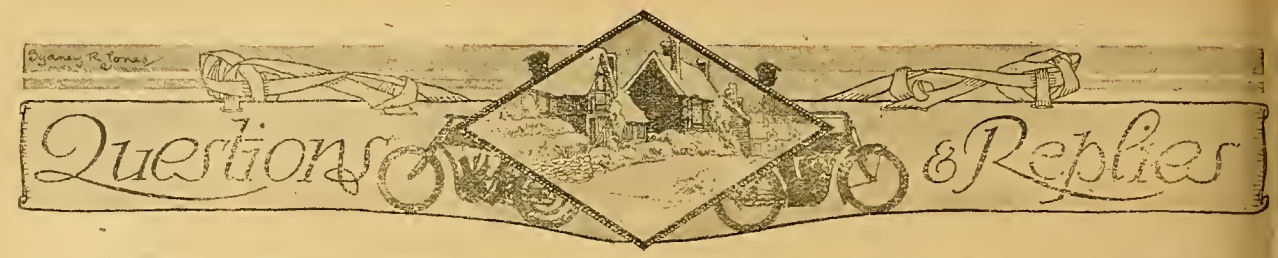
A Reply to "Ailette."

I should like to remind "Ailette" that the instances he adduces in his appeals and prophecies on behalf of the water-cooled engine all refer to rather abnormal conditions. The Mototri-Contal (rather a mouthful!) was run under conditions almost as bad as if the engine had been a stationary plant for producing electricity or shop power. Undoubtedly, if I wanted an engine to drive a dynamo or for other stationary



The 3½ h.p. Brown 85×85 mm. built for this year's Tourist Trophy Race.

work, I should demand water-cooling; and the "Mo., etc., as before." was a tiny engine, geared very low to propel a heavy load and ran very fast to maintain a 15 m.p.h. minimum; in other words, its work was a compromise between normal roadwork and power station work, and therefore abnormal. His Brooklands experiment also suggests quite abnormal work; the commercial motor bicycle engine is never asked to do twenty miles absolutely all out, and end by climbing a 1 in 4 grade—thank goodness; and if water-cooling beat air-cooling in such a test, the experiment would be all but valueless as applied to the commercial type of roadster. When "Ailette" was running his air-cooled tricar I was running a water-cooled tricar of slightly smaller engine dimensions. I admit the water-cooled type I patronised always beat his air-cooled make in timed hill-climbs, and that it was also a trifle more dependable for work on mountain passes; but there was little real difference between them in that respect, and a pretty nuisance I had with water cooling. That is the contrast in a nutshell.



A selection of questions of general interest received from readers and our replies thereto. All queries should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, E.C., and whether intended for publication or not, **must be accompanied by a stamped addressed envelope for reply.**

Horse-power Rating.

"According to the R.A.C. formula of h.p. you gave recently, an 85 × 88 mm. engine works out at 4.35 h.p., yet it is said to be only 3½ h.p. Would you please explain the reason of this. Formula used:

$$\frac{\text{Bore}^2 \text{ (inches)} \times \text{no. of cyls.}}{2.5} = \text{h.p.}$$

—J. McLAUGHLAN, Aberdeen.

It merely means that the makers of the machine slightly under-estimate the h.p. As a matter of fact, an especially good engine of the size stated can develop quite 5 h.p. running at the maximum number of revolutions.

Silence Desired.

I am shortly ordering a 5-6 h.p. twin Bat-J.A.P., and am particularly anxious to have it as quiet as possible. Kindly give me your opinion. (1.) Would it run quieter fitted with two silencers instead of one; that is, one to each exhaust pipe? (2.) Which is the best silencer? Can you recommend the Clair, or is there another that you think is better?—J.H.

(1.) If you have one good and properly dimensioned silencer it should be sufficient. One silencer is standard on the Bat, so that certain alterations would be necessary if you decide to fit two. (2.) We know of no silencer better than that mentioned in your query. It effectively silences the exhaust, and can be obtained with a variable cut-out.

Verifying Petrol Level. Sluggish Starting.

Please advise: (1.) How can I verify level of petrol in jet of B. and B. carburetter? I cannot see down the jet. (2.) Everything else being correct, could an incorrect level of petrol in jet account for my inability to get more than two consecutive explosions from engine? It is a 1908 machine, fitted with Roc gear and handle starting on rear axle. Spark is correct, plug points very close, and jet clear. Spark lever two notches from full advance, air lever closed, throttle half open. Have tried plugging one of the permanent air holes, but then get explosions (slight) in silencer. Piston and flywheels seem free, as I can turn handle at a good speed.—N. J. R.

(1.) Obtain a dummy jet from the makers with the top open. This will enable you to see the height to which the petrol rises. We also refer you to some useful hints in the article "Adjusting and Testing Carburetters," issue of January 10th, page 36. (2.) We should not say that the level in the carburetter would entirely account for the symptoms from which the engine is suffering, as we presume you adopt the usual course before attempting to start, viz., flood the carburetter by raising the needle. There are many reasons, such as ignition, timing, etc. We should recommend you to check over the timing, and see if this is correct, and especially examine the action of the contact-breaker. Probably the fibre ring is worn and the points are not separating properly. Make sure also that the platinum points are quite clean and flat, and try another plug.

Swilling the Crank Case. Engine Knocking when Starting.

(1.) I wish to clean the crank case of my single-cylinder magneto motor cycle, fitted with two-speed gear, free engine, and no pedals. How much paraffin should be injected into crank case? As I do not relish the idea of running the machine up and down for a few minutes, would it be quite safe to start the machine on low gear, switching into free engine immediately on firing, and allow it to run for a few seconds? Should the drain tap be left open during the process, and will it be necessary to dismantle the engine afterwards to clean cylinder? The carbon deposit has recently been removed from piston and cylinder head and valves re-ground. How often should crank case be cleaned? (2.) What is the cause of knocking when starting with magneto somewhat retarded? Does it point to a loose bearing or to the carburetter receiving too much air? Throttle lever quarter open, extra air closed, both main air intakes open. Machine starts easily enough, but knocks at slow speed, especially when starting under the conditions stated, and does not accelerate quickly. Machine gives a good turn of speed when fairly under weigh.—A. B. C.

(1.) You should put about a quarter pint of paraffin into the crank case. Yes, you could start the engine on the low gear and run it for not more than ten seconds, which will be quite enough to swill the paraffin round: then the drain tap should be opened and the dirty oil allowed to drain out. If the carbon deposit has recently been removed from the piston and cylinder head, there will be no necessity to dismount the engine again. The crank case should be swilled out with paraffin every 400 or 500 miles. (2.) The cause of the knocking is often difficult to account for, unless, of course, as you suggest, there is something loose. If you are satisfied yourself that this is not the case, we should say that there are deposits on the cylinder and piston or the magneto spark is timed to occur too early in the stroke.

Building a Tricar.

I am having a tricar built locally, and have decided upon a 5-7 h.p. twin-cylinder air-cooled engine. (1.) Is the power sufficient, in your opinion, without a change-speed gear? (2.) Do you recommend a Peugeot engine? (3.) I have at present a N.S.U. gear fitted. Would this gear stand the strain of a 5-7 h.p. engine?—P. C. H.

(1.) The power in question is sufficient for passenger work, but even if you had a 20 h.p. machine you could not manage to tour comfortably without a change-speed gear. A low gear enables you to start from a standstill, climb hills in populated towns slowly, and enables a machine to pick up again on a rise if hindered by a sharp corner or traffic. (2.) The engine is a good one and is largely used. (3.) We believe the gear in question will be strong enough, but it would be advisable to write to the N.S.U. Co. about this.

Main Air Supply Too Great.

I have a 4½ h.p. Humber tricar, and I always have a difficulty in starting the engine even after I have injected petrol through compression tap. Will you explain the cause of the engine not firing when I inject petrol? When the engine is set going it goes off at a great speed and will not run slowly at all. If I try to regulate it in any way it will stop, then I have a job to start it again.—G.M.E.

It seems very much as if the carburetter gets rather too much air, *viâ* the main air intake. We believe your machine has a Longuemare carburetter. If so, take out the air funnel, or choke tube, and fit one or two sizes smaller. Otherwise, if you fit a shutter for excluding the air temporarily, either wholly or partially, at the moment of starting, it would get over the difficulty, and also, if you partially close it, allow the engine to run slowly when occasion requires.

Chronic Misfiring.

I have been troubled with chronic misfiring in my 3 h.p. motor cycle for the last four or five weeks. The machine has plain coil and accumulator ignition. I have sent it to several firms, but have not got it right yet. I now have it with a large firm in one of the most important Irish cities, and they advise me to fit trembler coil ignition, which they say is the more satisfactory of the two forms of accumulator ignition. Please let me know your opinion on this matter. If the trembler coil will cure the evil I shall certainly have it fitted.—C. O. M.

Probably your trouble is due to the coil. Send it to a good firm of electrical engineers, and let them overhaul it, or borrow another coil of the same type and notice if there is any difference in the running with this fitted. You will not find a trember coil to be suitable for your machine until you have altered the shape of the contact breaker cam and retimed the ignition, and also to the fact that it will slow the machine down considerably, and be more wasteful in current than a good plain coil.

Deposit on Platinum Points. Leather and Rubber Canvas Belts.

(1.) There appears to be some white deposit on contact points of my 1907 Triumph magneto? Could you please tell me what it is, and how to prevent it? I have not noticed anything wrong with the engine, except that I am bound to retard ignition a little if going slowly through a town, otherwise the engine knocks. Two or three months ago I could always drive with firing lever fully advanced at any speed; in fact, I did not touch it at all, but used the throttle (B. and B. handlebar control). Bell crank very little worn, and points separate just over $\frac{1}{32}$nd of an inch. (2.) Would a Watawata belt be much trouble to keep in order, and does it or any other leather belt wear out the engine pulley very quickly? I am inclined to over oil, and it comes out round the pulley, so that I have to take off the rubber belt after a ride.—G. C.

(1.) The white stuff referred to is usually platinum dust caused by the sparking at the contact points. Trim up the points with a fine jeweller's file, leaving them quite flat and clean. The best way to reduce it is to keep the condenser connections clean (see diagrams in "Motor Cycles and How to Manage Them"). It depends upon how the magneto is timed whether it is necessary to retard the lever when running slowly, but in most cases it is necessary to retard the ignition when driving slowly to prevent the engine knocking. (2.) You will find the belt suggested in your letter to be quite a good and exceptionally long-lived one. Of course, it needs more attention than a rubber belt, and must be dressed occasionally with Collan oil. It will not wear the pulley unduly if you clean it periodically of grit and mud.

A Loss of Power.

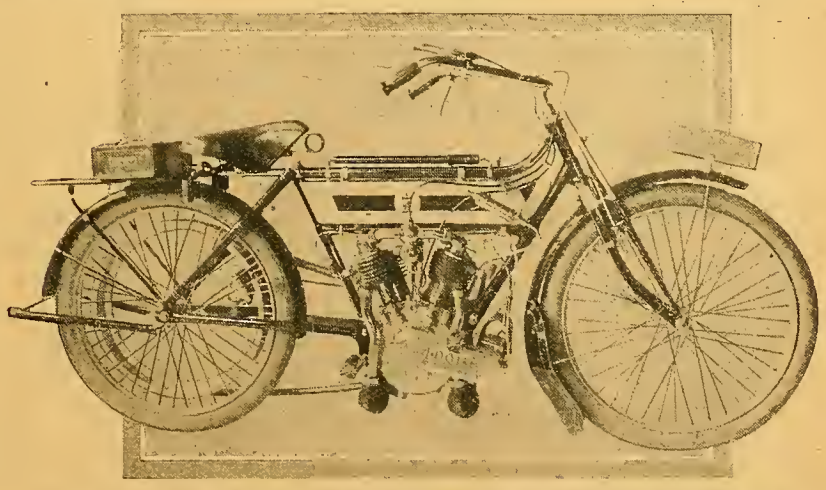
What is wrong with my 3 h.p. Lincoln Elk motor cycle? Although the compression is good, the machine will not look at the slightest hill, neither will it attain any speed on the level. The machine does not rush forward as it should when the throttle is suddenly opened, but it gathers a little more speed slowly. There is no "snap" in the sound of the exhaust, only a muffled sort of sound. All this appeared to me to point to a fault in the carburetter. But I have had the carburetter (B. and B.) off, and the jet, the slides, and the float are all in perfect order. Could you enlighten me as to the cause of the trouble?—P.H.

Your trouble is one for which it is most difficult to account without testing the machine, which is, of course, impossible. We should be inclined to think that the exhaust valve spring has broken, or, at any rate, suddenly lost its tension, or it may be that the exhaust valve is not lifting or closing properly, possibly due to wear in the timing mechanism. You can, however, easily see this by watching the action of the valve. You do not mention whether the petrol feed pipe and gauze are clear.

Wired-on or Beaded-edge Tyres. Registration.

Kindly advise: (1.) I am about to order a Tourist Trophy mount. Is the reinforced wired-on Dunlop tyre all right, or would you prefer beaded-edge tyres? (2.) My registration number is AJ 57. I am shortly leaving this district (Yorkshire) for Glasgow. Shall I have to register the machine there, or may I keep my old number, which I would like to do?—A. S. C., Sowerby Bridge.

(1.) Personally, for all-round work and ease of detachability we advise the beaded edge in preference to wired-on tyres. The latter, however, are generally agreed to be faster, and less likely to blow off under severe strain, such as turning corners at high speed. (2.) We are not quite clear as to what you mean with regard to your number. If you are buying a new machine you cannot transfer the number from your old machine unless you cancel it before the machine is sold. Then, if you write to the registration authorities and ask leave to retain your number, you may be allowed to do so on payment of the usual 5s. fee when registering the new machine. You may register a machine in any county or borough you like, though the driving licence must be taken out in the district in which you reside.

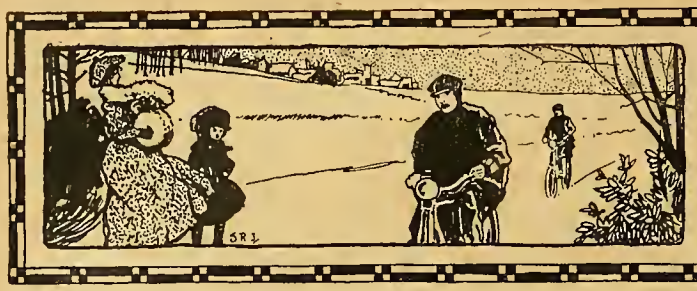


The new model 5 h.p. Twin-cylinder T.T. Dot, to be exhibited at the Manchester Motor Show, which opens on Friday. The engine is a Peugeot, carburetter Amac, and magneto Simms.

SPARKLETS

In the issue of January 31st under the heading of "Some Features of American Motor Cycle Design," we illustrated a "Curtiss-Marvel" piston with lubricating channels arranged in spiral form from top to bottom of the piston. The Norton Mfg. Co., Ltd., Floodgate Street, Birmingham, point out that they also use this system on piston and rings, and first adopted it four years ago.

The Laurin and Klement Motor Co. have lately produced from their works in Jungbunzlau a new light tricar. The frame is of substantial construction, the engine is of 4 h.p. water-cooled with thermo-syphon circulation, the transmission is by chain from the engine to the countershaft, and thence by chain to the rear wheel. The two-speed gear and clutch are carried on the countershaft, as is also the starting handle. The firm of Laurin and Klement, which is one of the most successful on the Continent, is a conservative one, as it still supplies a surface carburetter and low tension magneto. This probably is the sole reason why the Laurin and Klement is an unpopular mount in England, as surface carburetters and low tension magnetos on motor cycles in England are reckoned to be as dead as the proverbial door-nail. If the firm would render their mounts slightly more up-to-date they should command a ready sale in this country.



SPRING FORK DESIGN.

By G. DOUGLAS LEECHMAN.

AMONG the undoubted advances in motor cycle design apparent in this year's models, the improvement in spring forks is one of the most noticeable. As a rule, the direction of movement is a combination of the upward and backward directions, as it should be, the angle of the steering axis itself forming a very good compromise. The parallel ruler action (see fig. 1) affords this line of motion approximately, and that device deserves the general

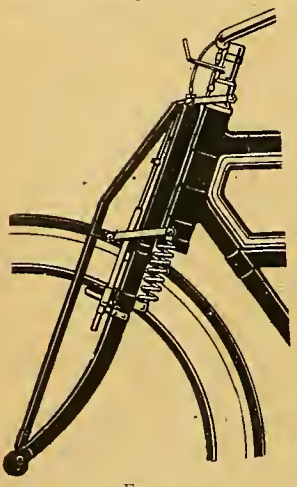


FIG. 1.

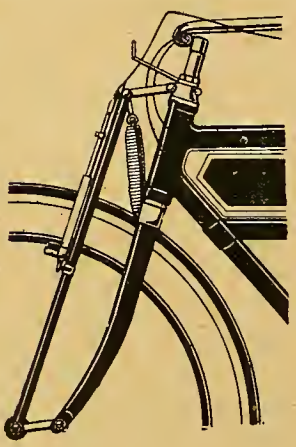

FIG. 2.

recognition it has received. Side play has also been carefully guarded against in most of these anti-vibrators, but there is evidently some diversity of opinion as to whether this is best attained in the parallel ruler pattern by applying the lower links at the bottom of the head or at the wheel axle.

With the former construction the lower links have a basis formed by the ex-fork crown which is integral with the upper one, and therefore free from shake, but any looseness in the bearings of the links is multiplied several times at the point of contact between the tyre and the ground.

With the latter alternative (fig. 2), what I may call the original or rigid fork is retained in its entirety, and the lower links are jointed to its extremities. This confines the amount of lateral looseness at the ground to an increase of about 40%. But, on the other hand, there are two more or less serious objections which can be raised against this construction, although the fork itself may be slightly lighter.

The fact that the free ends of the fork sides, deprived of their usual stiffening bond in the form of the wheel spindle, provide a very unsubstantial base on which to pivot the links, and the fact that the arrangement precludes the possibility of coupling the links together rigidly at their back ends, both allow a considerable range of lateral give that is perhaps even worse than a definite small amount of slackness. In this type of spring fork, in view of the absence of a through spindle at the rigid fork ends, the rigid fork sides should be made of increased lateral stiffness.

Another disadvantage (fig. 3), attending the fitting of the lower pair of links at the wheel axle, arises from the fact that it is necessary to introduce a joint between each link and the forward fork, as the fork must move in the direction of its length, and not swing through an angle with the links.

A Choice of Two Evils.

If the wheel axle is fixed to the forward fork ends by nuts in the usual way, the links must be free to turn relatively to the axle. This not only means that the links are free at both ends, but that they are capable of independent movement (fig. 4)—a sure source of side-play. On the other hand, if the links are locked rigidly to the wheel spindle—as they should be to ensure their moving together—the forward fork must be jointed at the bottom and thus lose a considerable amount of its steadying effect. This is probably the lesser of the two evils, but in setting out the joints their axes should be arranged in the line of the fork.

If the forward fork is jointed to the links there will be a rising and falling movement between the fork and the wheel, which will interfere with the action of the front rim brake, even if it does not altogether preclude the possibility of fitting such a brake.

Effect of Spring Forks on Steering.

In adapting an anti-vibratory device to the front forks, a good many designers have apparently omitted to consider the effect of their devices on the steering of the machines. Although an ordinary front fork curves forward at the lower end, yet a steering wheel

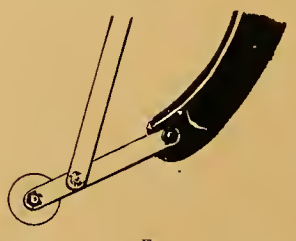

FIG. 3.

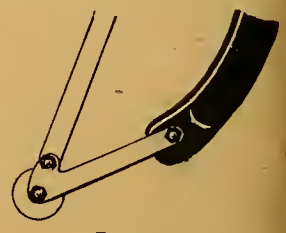

FIG. 4.

in a properly-designed machine has a trailing action. If the axial line of the ball-bearing steering head be continued downwards, it will, no doubt, pass behind the centre of the wheel, but it will pass in front of the lowest point of the wheel (fig. 5), and that is what matters, because that is where the wheel makes contact

ring Fork Design.—

ith the ground. The fork pushes the wheel forward om the centre, and the ground acting on what is really ie back part of the wheel—*i.e.*, relatively to the steer- ig line—tends to hold the wheel straight in the central lane of the machine. If the steering head were ertical, the fork would have to be curved back to get is trailing action, but as it is in practice, sloped onsiderably, even the forward curving of the fork oes not entirely cancel the "lead" on the steering.

The steering line should fall about two and a half

FIG. 5.

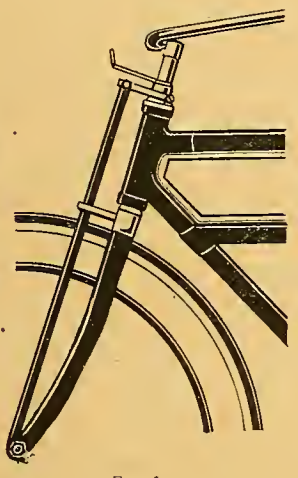

FIG. 6.

three inches in front of the point of contact between e wheel and the ground. The mistake some of the esigners have made is that in adding the spring evice they have set the wheel some inches further rward, and have thus prevented the trailing action g. 5).

Motor bicycles having such forks would have no tomatic tendency to balance and run straight, but ould have to be steered positively all the time. The rider might not be conscious of the trouble, but he would probably suffer a good deal more strain in the arms during a long run than on a machine with perfectly-designed steering head and forks. If the springing system involves a forwardly arranged wheel, some or all of the curve should be taken out of the forks to compensate for it. This will bring the wheel back into the old position relatively to the steering axis and restore the automatic balance.

That Wretched "Old Man of the Sea,"

the horizontal top tube, not content with spoiling the back frame, comes in and complicates the spring fork problem also. For, as the front wheel has to be free to rise and fall relatively to the main frame, it is necessary to leave plenty of clearance between the wheel, or rather the mudguard, and the bottom tube. Hence the front end of the tube has to be brought up nearer to the top one, and the connection of the frame comes dangerously near to the treacherous "pin joint."

The raising of the bottom tube cannot very well be avoided, but there is no mechanical reason why the top tube should not be sloped upwards to a corresponding extent.

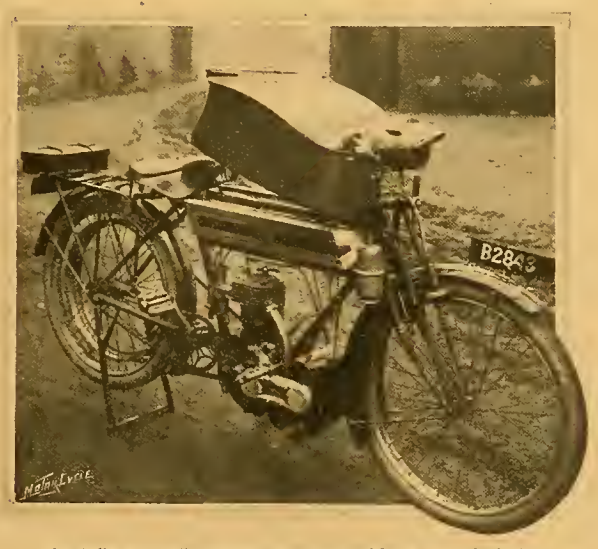
Anti-vibrators Indirectly Strengthen the Forks.

Lastly, I may refer to the influence of the springing on the strength of the fork. Almost, if not quite, all anti-vibrators strengthen the forks indirectly by saving them from violent shocks; the stresses are dissipated so that there is not the same excuse for fork breakage at any particular point, such as the stem or crown. This is a valuable gain, but apart from it, though the addition of, say, a supplementary guide fork may give an appearance of increased strength, such is generally one of those appearances that are proverbially deceitful. In one or two systems an additional tube is fixed in front of the head, and is connected to the stem top and bottom. This is certainly a source of increased strength, but structurally many spring forks are weaker than rigid ones (fig. 6). In securing comfort it is advisable not to overlook the element of safety.

A WEATHER SHIELD FOR THE HANDLE-BARS.

A NEW design of weather shield for the handle-bars called the Molineux is illustrated herewith. During thorough tests in the recent inclement weather the inventor (Mr. G. F. oleman, 88, Waterloo Road, Wolverhampton) tells he found it to be an admirable attachment from iny points of view, as it protects not only the hands d arms, but also that vulnerable portion of the body, e "waist line."

The Molineux shield affords ample protection while lowing complete freedom of movement to the rider. does not in any way necessitate alterations in stan- rd construction. It is made of thick patent leather ounted on a rigid sheet of fibre, which is ed to the handle-bar by means of four plated brass ips. The fibre sheet is adopted in preference to framework, as the latter would produce unsightly llowing. The two clips nearest the handle grips ise the shield to sufficient height to allow for opera- n of the levers and horn, and any instruments, such speed indicator or watch, can be fixed on the out- le by cutting a slot in the shield to take their clips.



The Molineux weather shield. Note the position of speed indicator.

Scottish Taxes for Motor Cycles and Traction Engines.

A COMPARISON BY "ROAD SURVEYOR."

MOTOR cyclists have been advised in recent issues of *The Motor Cycle* to renew their local taxation licences in counties where consideration is shown to motorists, and from this I infer that the county authorities in England and Wales get this money for the maintenance of the roads. As far as I am aware, this is not the case in Scotland, where such licences are paid to the Inland Revenue authorities, so that we in Scotland have no chance of going in for "retaliation" against those counties where the persecution of motorists seems to be the chief aim of the police. Why should this be so?

I should also like to point out that in Scotland a man may own as many traction engines and motor waggons as he likes, and is not called upon to pay a single penny for licences. Surely there is something wrong here! English traction engines can be used in Scotland without paying a licence, but Scottish traction engine owners have to pay a heavy licence before their engines can haul a single ton on English soil. Another case of free trade and protection!

My motor cycle (or a motor car, if I could afford it) is indispensable to me in carrying out my duties as a road surveyor in a proper manner, and almost as necessary to me in earning my living as a traction engine is to its owner. If the licence on motor cycles be increased to £1 plus 3d. per gallon on petrol, I have no means of recouping myself for the extra outlay, whereas a traction engine proprietor would merely have to raise his charges for hauling, when the cost of the licence would fall on those who employed him, and these are really the ones who ought to pay. It is no exaggeration to say that one traction engine with loaded waggons will do more damage, on certain days, in one passage over a road than many hundreds of motor cycles would do. In the case of a badly made country road, one traction engine will do more damage than thousands of motor cycles. It is only when the roads are very dry that motor cycles do any appreciable damage, as then they tend to loosen the surface, but this only happens when a large number travel together at speeds in excess of the legal limit. When a poor motor cyclist commits a technical offence, such as exceeding the speed limit, ever so little, in one of the numerous police traps, then he usually considers himself lucky if he is let off with a £4 or £5 fine and expenses. He may have exceeded the speed limit unknowingly, but how often do traction engines exceed their lawful speed limit, and wilfully too? Do we ever hear of police traps for them! I've never heard of one!

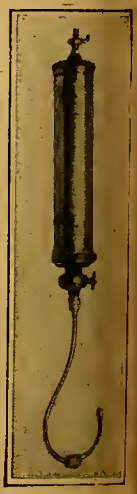
Traction engine drivers in this part of the country (N.B.), in deliberate contravention of the law, fit metal studs to the wheels to enable them to travel on the roads when it is frosty weather. Very often it is only a thin layer of the road surface that is frozen when very serious damage is done to the road. These men are never fined for this deliberate contravention of the law or the serious damage they do, and again I ask why? The poor ratepayer has to pay for it all, and when he receives his demand note he turns round and blindly blames motorists for the extra cost.

Motor cyclists at least can have an easy conscience and make full use of the public roads, for I can assure them they pay dearly for their share of the wear and tear of our highways.

MIXING THE MIXTURE.

"MELANGE" recently suggested inserting in the inlet pipe of motor cycle engines a coil spring for the purpose of breaking up the petrol and more efficiently mixing the mixture. Several readers have asked what type of spring "Melange" found most suitable, and in response to our query he says that what he finally used was an exhaust valve type of spring, fitting the pipe fairly tightly, and having the effect of corrugating the walls of the inlet pipe, and so introducing "skin friction" against the travel of the gases. A motor cyclist who is interested in the idea differs from "Melange," and thinks that a spring which fits close to the walls of the pipe with a free passage through the centre of the coil would be of little use, but if the spring were made in the form of a double taper it might possibly be efficient in breaking up the mixture, but would offer a certain amount of obstruction. He adds further that a single short taper spring with the small diameter of the coil nearest to the carburetter, in his opinion, would give the best results. Fitting a spring or anything else in the inlet pipe should be undertaken with the greatest care, as proper methods should be employed to prevent the spring being sucked into the inlet valve. If any other readers have experimented in this direction we shall be pleased to hear from them.

AN AUXILIARY PETROL TANK.



THE accompanying half-tone shows an auxiliary petrol tank which should prove very useful to agents and depot managers in showing customers new motor cycles running on the stand without the trouble of filling the regular fuel tank.

As may be seen, it is simply constructed from the tube of an old inflator and a few old connections that can be found about any cycle shop, a duplicate petrol feed pipe is then coupled direct to the receptacle, the other end fitting the carburetter union. The spare tank is merely hung by a piece of string to the frame to avoid scratching the enamel.

Riders who dismount their engines for overhauling often find that they either start with difficulty afterwards, or fail to give their full power, due, apparently, to incorrect carburetter adjustment, though the latter part of the machine has never been altered. The real cause, however, may often be traced to failing to screw up the carburetter unions properly, thus allowing the engine to draw in air *viâ* the loose unions.

LETTERS TO THE EDITOR

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, E.C., and should be accompanied by the writer's full name and address.

Bore-stroke Ratio and Efficiency.

[4563.]—I have read Mr. Scott's reply to my letter on his criticism, but do not propose to continue the discussion, nothing having transpired to disprove my arguments showing the advantage in stroke power of an engine with stroke greater than the bore diameter. I have stated my case impartially, with reason, and as clearly as possible, and now leave your readers to form their own conclusions from the matter written on both sides, trusting that the popular but fallacious objections to the long stroke may be to some extent removed.

I beg to express my thanks for your courteous treatment, and for the use of your valuable space.

JAS. L. NORTON.

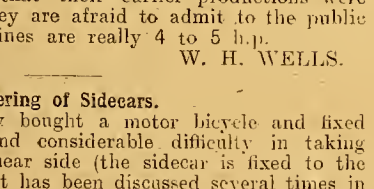
Cubical Capacity and Horse-power.

[4564.]—If one looks through the specifications of single-cylinder motor bicycles shown in *The Motor Cycle* Buyers' Guide there will be found so-called 3½ h.p. single-cylinder machines varying in cylinder capacity from 402 to 558 cubic centimetres. I think many readers, as well as myself, would be extremely interested to know why it is necessary to have this extreme variation in cubic capacity in order to produce a 3½ h.p. single-cylinder motor cycle engine. If the 402 c.c. can be made so as to develop 3½ h.p. what is the use of forcing on the public a lot of additional bulk and weight, which, according to the makers' point of view, accomplishes no more than the smaller engine. A few years ago several well-known makers of motor cycles offered for sale so-called 3½ h.p. machines; within the last two years they have considerably increased the capacity of their engines, yet they still call them 3½ h.p. From this we can only believe that their earlier productions were exaggerated, or that they are afraid to admit to the public to-day that their machines are really 4 to 5 h.p.

W. H. WELLS.

Steering of Sidecars.

[4565.]—Having lately bought a motor bicycle and fixed a sidecar to it, I found considerable difficulty in taking corners to the left or near side (the sidecar is fixed to the left side). As this point has been discussed several times in your interesting journal, I venture to give my explanation of the difficulty, and how I overcame it. I should be interested to hear if other motor cyclists have arrived at the same conclusions.



The dotted lines represent two straight edges placed beside the wheels, a few inches from the ground. If the sidecar wheel is quite in line with the two motor bicycle wheels, there is a drag to the near or left side when travelling in a straight line, and if the sidecar wheel points in towards the front motor cycle wheel too much it is very difficult to steer to the near side. The sidecar wheel, though free, is really driven forward by the fixed axle from the motor cycle driving wheel.

After a good many adjustments, measuring as indicated I arrived at the best position. The length of a motor cycle wheelbase and the width of the sidecar will have a considerable influence on the position, so that the difference fore and aft will be less or greater than the 1½in. on my machine.

HERBERT PORTER.

An Excellent Hill-climber.

[4566.]—There is a motor cyclist in this neighbourhood (Bishop's Stortford) who owns a machine, the behaviour of which has compelled me to ask, through the medium of *The Motor Cycle*, for a little information. The machine is a "Wolf" pattern lightweight, fitted with an engine of the Stevens type, with outside flywheel. The owner has added a two-speed gear, about 5in. in diameter, and of about 3 lbs. weight, and has dispensed with the pedalling gear and fitted footrests. The gear gives two speeds and a free engine. With this air-cooled tea cup of an engine, and a speed gear not so big as a penny bun, he calmly drifts up local gradients that stop dead four-fifths of the local heavyweights and 3½ h.p.'s. The engine, he informs me, is more than four years old! What is the meaning of it all? Is the motor cycle manufacturer retrogressive, and shall we in due time come to traction engines?

C. W.

Tools and Spares to be carried.

[4567.]—Now that the commencement of the active riding season is at hand there is a matter, I think, that should be given at least a little consideration. I refer to the question as to what constitutes an efficient equipment of tools and spares to be carried by the rider of an up-to-date touring motor cycle. At first sight this may appear a matter that can be very well left to the individual, but any rider will agree, when through neglect on his part to carry some tool or spare that an emergency may make indispensable, and he becomes dependent upon the resources of the good Samaritan, that the contents of various bulging and greasy bags, willingly submitted to his inspection, are rarely able to supply what is required.

This points to the fact that unnecessary tools, etc., are indiscriminately bundled into our toolbags on the off chance of their coming in useful some time or other, instead of only such articles as a careful analysis of probable requirements may suggest to the practical rider. It would be interesting to learn from your readers what they consider an ideal kit. I have read with much pleasure Mr. D. S. Baddeley's account of his 1,700 miles ride; a statement as to the amount of "running expenses" incurred would add to the instructiveness of his article.

R. WENTWORTH COOK.

Lightweights v. Heavyweights.

[4568.]—*Re* letter 4545 in the issue of January 31st. I see a Mr. Case Moriss thinks a modern 3½ h.p. would not get up Maenporth Hill. I ride a 1909 Triumph and have a friend who rides a 1909 Rex. If Mr. Moriss is willing we will meet him at Maenporth one fine day and have a try at it. I live within five miles of the hill and have been riding six years, but have had no occasion to try the hill in question. In conclusion, could you make *The Motor Cycle* bi-weekly instead of weekly? I read every word and enjoy it.

C. MARSHALL THOMAS.

[4569.]—In reply to letter 4555, I think Mr. A. D. Tyler makes rather a bold statement when he says that he doubts my statements, nor has he any authority for saying so. Perhaps he thinks I am in the habit of making public statements which are not correct. However, he says, might he ask what lightweights I really have ridden? I have ridden the following: Motosacoche (I think five machines). Rex (two machines), Moto-Rêve, F.N., Quadrant, Ariel, and a lightweight machine fitted with a Werner engine. I did not own any of the above machines, but rode them quite long enough to form an opinion; by that I mean that I rode

the machines some days, and did not just jump on for a spin. Perhaps Mr. Tyler is one of the type I mentioned as upholding the lightweight. If so, no doubt he has had longer and wider experience than I.

B. G. DURKIN.

[4570.]—I am at all times interested in reading criticisms and the general useful information that *The Motor Cycle* contains from time to time. But I am unable to digest with comfort such remarks as are contained in the views put forward by B. G. Durkin in respect to the question of lightweights and heavyweights. All men who indulge in motor cycling, or any kind of sport or pastime, should pride themselves on keeping fit, strong, active, cool headed, and of good nerve, and I am pleased to know that your correspondent "B.D.G." fulfils these qualifications so thoroughly. At the same time I would respectfully remind him that he should not set down these qualities as being unapproachable by married men, or men of forty years of age—such comment is uncalled for, disrespectful, and unwarrantable.

I do not know Mr. B. G. Durkin, but I have the pleasurable acquaintance of many riders between the ages of thirty-five and forty-five years, who, although they are riders of lightweight machines, are not a bit nervous at crossing the saddle of a 5 or 7 h.p. motor, and control it as well as most riders. The sole reason for adopting a lightweight is to obtain greater comfort, ease of control, pleasure, and economy, and the lightweight is more suitable for business purposes. In the cases I mention the heavier and more powerful machine is not adopted because of lack of nerve, strength, or pluck, as "B.G.D." implies. I hope he may long retain his present high standard of fitness, and when he contemplates taking unto himself a wife, or is bordering on the forty years limit, he will perhaps think of the time when he possessed all those great qualities he mentions, and join the ranks of the lightweight enthusiasts, of which I am one. In conclusion, I am riding a 1910 2¾ h.p. Douglas. I ride it daily in all weathers in the South Wales districts, which are very hilly and rough in many parts. It carries me in comfort, and I would not change it for any other mount I have met with of greater power. My weight is 12½ stones, I am thirty-eight years of age, and up till the present I retain all my old cycle racing day qualities of strength, pluck, and endurance. Not bad for a lightweight enthusiast.

C. H. SIMONS.

The Transmission Question.

[4571.]—With regard to the discussion on the above question in your columns during the past few weeks, there is one point regarding belt transmission which I do not think has been mentioned.

I find, for instance, that a first class rubber and canvas belt, such as the Gloria, 1in. or 1⅛in. wide, lasts longer on my present 7-9 h.p. machine than the same size and make of belt did on a previous 5 h.p. and lower. This I ascribe to the fact that I now gear 3¼ to 1 for solo work and 4 to 1 with sidecar, as against previously 4 to 1 and 4½ to 1 respectively. The lower gear and therefore smaller engine pulley required on a low powered machine has a worse effect in cracking and breaking up the rubber belt than the extra kick of a larger and higher geared engine, even with increased speed and weight of the machine.

For a machine over 3½ h.p. I think there is nothing to touch a good rubber belt, but below this power, for the before mentioned reason of the lower gear required, a leather belt such as a Watawata is more suitable, there being also less power lost in bending.

I do not doubt the fact that Mr. Pratt, together with other chain enthusiasts, can start their bicycles and sidecars from a standstill provided they have a decent clutch, but in my opinion, for prolonging the life of pulley bearing and machine generally, combined with comfort and silence, the belt is superior to either the shaft or chain drives, as at present fitted. I have used the Whittle chain belt, but think to make it the equal of the rubber variety for both comfort and wear, it should be fitted in conjunction with some form of spring or slipping drive, on top gear at any rate.

I might mention that I always remove the belt from the pulleys after the finish of a ride, except in very wet weather.

For racing, chain or shaft is no doubt faster than any belt drive.

VIVIAN OLSSON.

A Lightweight Converted to V Belt Drive.

[4572.]—Herewith is a snapshot of a 1¾ h.p. N.S.U. fitted with direct V drive by ⅝in. S.G. belt, about which I sought your advice some weeks ago. This belt has run now nearly 2,000 miles, and is still in good condition. As you may see by the photograph, not a bit of the rubber is gone from the sides.

I should also like to recommend a good plug. The one fitted to my N.S.U. has run 1,600 miles and still fires on first turn of pedals. It is a Darop. The centre piece is solid like an acorn, and fires all the way round to the body of the plug.

N.S.U. lightweight converted to direct V belt drive by a reader residing in Central India. (See letter No. 4572.)

This photograph may help some of your readers who own lightweights and are subject to belt troubles. The cost of the alterations would be about £1 at home, but it cost me £2 in Calcutta.

C. A. HOLLAND.

Fort Allahabad, Central India.

The A.C.U. Quarterly Trials.

[4573.]—I was surprised to read in the report of the Quarterly Trials that W. Pratt received full marks for Dashwood Hill, and more surprised at his being awarded a non-stop, as it is well known that he fell off his machine on Dashwood. In the Quarterly Trials last October, when sent off, my engine refused to fire until I had got some distance, so I went back and requested another start, which was refused. If this rule is enforced with one, it is only fair that it should be with all.

I also see that G. Lee Evans and W. O. Bentley are awarded non-stops. I was not aware that getting off and running alongside machines was allowed, neither did I come across a lot of thick traffic as reported. J. Gibson failed on Dashwood Hill, but I see he gets a non-stop. The 3½ h.p. Premier (G. E. Stanley) is also awarded a non-stop, although I understand traffic caused the rider to dismount twice. The 3 h.p. Wanderer (A. V. Deacock) side-slipped on Dashwood, but gets full marks. H. H. Bowen (5 h.p. Indian) broke footrests before Banbury, and repaired chain after leaving that place, and gets credited with one stop only. One non-stop man smashed his footrests without coming off (some dubious people would not believe this).

If these trials are to be of any use to the public or to the trade, I consider they should be carried out in a more fair and businesslike manner.

I had the misfortune to fall and break a pedal off and slightly damage some other parts, which was the reason of my being credited with failing to climb Dashwood and Rectory Hills. I do not complain of this, but in the interest of the firm who pays my expenses I must complain when favours are granted to others and refused to myself.

ELI CLARK.

[4574.]—I have carefully examined the official results of the Quarterly Trials, which were published in last week's issue of *The Motor Cycle*, and I find that I have been awarded only ten marks out of a possible twenty for "General Excellence of Design." Others have been awarded more, and others less. Of the latter I will not speak. What I am anxious to know is this. The Bradbury motor cycle is generally admitted to follow standard lines as regards general design. Now this machine also has special features of its own as regards design. Three of the most significant are: (1) Extraordinary accessibility to interior of engine; (2) detachable and adjustable bottom bracket; and (3) detachable rear mudguard and carrier. Why were these excellent points overlooked by the judges, or rather, perhaps my question would read better, Why were marks deducted for these points? I understand the machines were examined at the end of the trial, when the design was noted. Now my machine was not then examined, because I retired early in the trial (with a damaged arm through a fall).

Another question that I should like answered is, Why was a certain rider awarded full marks for climbing Dashwood Hill when, owing to sideslip he fell, and then finished the climb by pushing his machine? I merely ask this question because I reached the summit under the same circumstances, and was awarded no marks at all for the climb.

The competitor in question is as much surprised at the result as I am. A. T. STANTON.

[As regards our correspondent's first query, the Competitions Committee has now decided not to award marks for "General Excellence of Design." See page 124.—ED.]

Causes of Overheating.

[4575.]—Two things I notice are not impressed upon motor cyclists who complain of overheating after trying various adjustments. One is leaky induction joints, which in many cases look perfectly gas-tight, but are not. This can be tested by blowing down induction pipe (valve held on its seating by spring or otherwise), when leaks will be manifest. The other special thing is, novices are apt to take down cylinder and fail to replace washer between cylinder and crank case (if any), or sometimes throw away washer and fit a thinner one, under the impression that it makes no difference.

I myself have seen and ridden motor cycles with cylinder and plugs red-hot, and the cause has been traced to the said washers being removed, and thus raising the compression. P. G. J.

Metal for Exhaust Valves.

[4576.]—As a novice, I should be interested to know, *apropos* of "Ixion's" remarks on metallurgy, whether anyone has ever tried making exhaust valves, or larger parts of a motor cycle engine, of one of the new air-hardening tool steels. I believe these steels will work quite well when red-hot, and they certainly do cut far faster than the old steels. Possibly there would not be enough elasticity, and the head might be inclined to fly off, but cast-iron is not so very elastic, and it seems to be one of the favourite metals.

Tool steel is, I believe, difficult to work, but I do not see why it should not be possible to forge a valve to shape, under a die, and grind it true. Very likely it would need careful adjustment to get the right spring tension, not to crack the head off.

I should like to try the experiment myself, if it has not been done before, but my present valve has given no trouble yet, and as a beginner I believe in "letting well alone."

I hope to hear something on this interesting subject from someone who has had more experience. C. M. B.

Morgan's Petrol Turbine.

[4577.]—In *The Motor Cycle* for last week is a reply to some critics by the inventor of the above engine, in which he seems to think that the pressure of the exploded gas in the combustion chamber will drive the rotor. I will try to explain why this is not so. In every engine which works by fluid pressure, as Mr. Morgan says his engine is meant to do, the volume of the working chamber is variable, as, for instance, in a reciprocating petrol engine cylinder, the movement of the piston changes the volume of the space containing the working fluid. Now in the Morgan turbine, the combustion chamber has a constant volume, and, therefore, the pressure of the contained gas can do no work. Mr. Morgan says that the pressure acts on the "base" of the chamber. If it acted on the base only, well and good, but, unfortunately, it acts equally in every direction, and so the pressures on the two sides of the wedge-shaped combustion chamber exactly balance. I think he refers to the action of an injector in his illustration of a steam boiler feeding itself, but the cases are entirely different. The injector takes steam containing a large amount of energy in the form of heat, transforms the heat into kinetic energy, which energy is then used to drive water into the boiler, but notice that because of inevitable losses, the energy contained in the steam as heat is considerably greater than the energy in the water.

One question: If the heat lost is "very great," where does the efficiency come in? The internal combustion engine, whether turbine or reciprocating, is a heat engine, and the more heat transformed into mechanical energy the greater is the efficiency of the engine. PERCY J. STIRRUP.

Wired-on v. Beaded-edge Tyres.

[4578.]—I was very interested to see Mr. F. C. Mustard's letter [4527] in the issue of January 24th on the above subject, as, coming from so experienced a rider, it must command respect. I am entirely in agreement with him in everything he says about wired-on tyres, and his experience is exactly the same as mine, in that he finds wired-on tyres vastly superior to the beaded edge variety. May I suggest to him that he fits a chain loosely across under the mudguard; he will then do away with nail punctures.

"Ixion's" remarks in your issue for December 20th are very interesting, and doubtless in the main correct. I have yet, however, to experience a broken wire. The only two cases I know of were on pedal cycles, and were caused by gross carelessness.

Mr. G. Lobb in letter 4477 writes of friction between cover and rim with wired-on covers. What does he mean? Also why does he let his rims get rusty inside, and so damage the air tube? Paint is cheap, and so is tape!

I have to thank Mr. R. Wentworth Cook for his letter [4449]. It is doubtless a fair statement of his experiences. I do not agree with him regarding levers chafing the fabric of wired-on tyres. This may be because I generally find my fingers sufficient, or at most a gentle application of a "One Minute" lever. The trouble in the past has been that riders have not understood the principle of the wire and rim.

HAROLD KARSLAKE.

EXPERIENCES WANTED.

"F. W." (Sheffield) desires owners' opinions of the Wilkinson T.A.C., as regards finish, quality, and running.

"A. P." (Bristol) would like readers' experiences of the Mabon clutch on a 6-8 h.p. motor cycle and sidecar.

"S.J.S." (Exeter) desires users' opinions of the 8 h.p. Bat with P. and M. gear for use as solo and sidecar machines.

"X." (Great Yarmouth) would like readers' experiences with the Whittle Link Grip belt. Does it wear the pulley unduly?

"J. S." (Glasgow) would like riders' opinions of the two stroke twin-cylinder Scott as to general reliability, speed, and average petrol consumption.

"F. H." (St. Petersburg) desires an amateur's experiences with a 5 h.p. Indian, especially as regards riding comfort and easy starting. "F. H." would also be pleased to exchange notes with motor cyclists in Warsaw and Moscow.

Owing to the fact that the business of the Bosch Magneto Co. is rapidly increasing, due to the great popularity of its magneto, the company will shortly remove to more spacious premises at 40-42, Newman Street, Oxford Street, W. The new home of the Bosch magneto consists of a large garage on the ground floor, commodious offices on the first floor, and spacious and well lighted repair shops on the upper storeys.

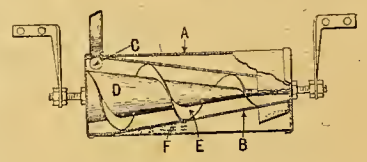
Readers who are on the look-out for a two-speed geared motor bicycle which will haul a sidecar will be interested to know that at the Phelon and Moore depot, 12, Mortimer Street, W., a P. and M. fitted with a sidecar is at all times ready for a run either in London or to any of the well-known hills in the district. The 1910 catalogue of the P. and M. two-speed chain-driven motor bicycle is ready, and can be supplied on application to the above address.

RECENT PATENTS

By ERIC W. WALFORD, F.C.I.P.A.

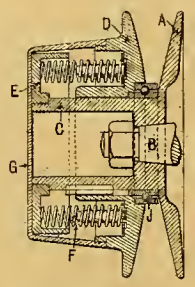
An Exhaust Silencer.

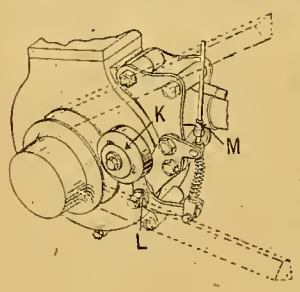
The silencer comprises a cylindrical outer chamber A, which contains a conical casing B, into which the gases pass from the exhaust pipe C. Within the casing B is a conical baffle D, which is provided with helical walls E, which deflect the exhaust gases towards the smaller end of the casing B through which they pass into the space within the cylindrical chamber A, passing thence to the atmosphere through the apertures F.—H. C. Gibson, No. 9,969, 1909.



An Automatically Adjusting Pulley.

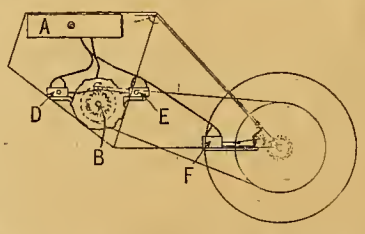
The variation in the tension of the belt which follows the variation of load on the engine is utilised to automatically adjust the movable flange of the engine pulley. The flange A is secured to the engine-shaft B, and carries a sleeve C on which slides the movable flange D. Upon the outer end of the sleeve C is screwed an annular cap E, between which and the movable flange D are arranged a number of compression springs F. A dust cap G carried by the movable flange D encloses these parts. A single track ball bearing J is arranged upon the sleeve C, and when the flanges are separated to their greatest extent a free engine is provided, the belt remaining stationary upon the outer ring of the ball bearing J. Hand-operated mechanism is also provided, and comprises a roller K, pivoted at L, and adapted to be forced between the pulley flanges by an operating rod M.—W. J. Lloyd, No. 19,697, 1908.





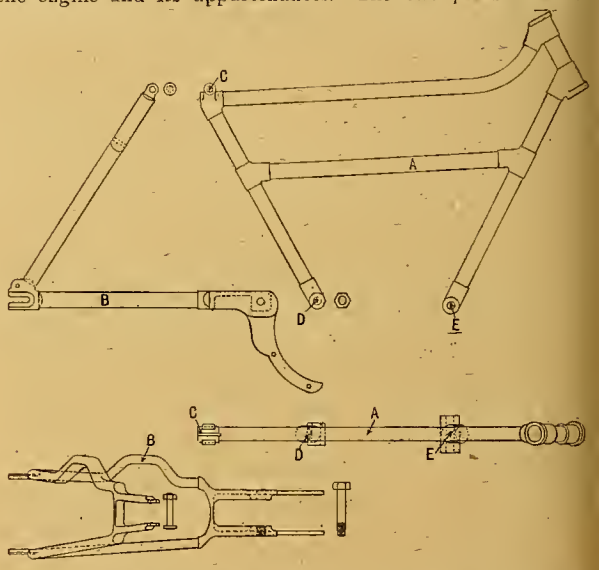
Perpetual Motion (?).

By this invention it is proposed to use compressed air to propel the machine, the power supplied being used at the same time to operate pumps whereby the air compression is maintained. Upon the bicycle is mounted a tank A supplying air to a turbine wheel contained in a casing B. The spindle of the turbine wheel is provided with the usual driving gear on one side, and on the other is geared to air-compressing pumps D E. An auxiliary air pump F is carried on the lower forks, and adapted to be geared to the rear wheel, so as to operate when free-wheeling. The inventors state that the initial pressure having been obtained by means of a tyre inflator or other pump, the compressed air may be admitted to the turbine wheel, rotating it, and so propelling the bicycle. At the same time the air pumps D E are driven, maintaining the air pressure in the tank A, and incidentally solving the problem of perpetual motion.—F. Adams and J. Trowles, No. 742, 1909.



A Divisible Frame.

The frame is divisible into two main parts—the front part A which carries the tanks, and the rear part B which carries the engine and its appurtenances. The two parts when in position are bolted together at the points C D E. The construction facilitates transport and permits of the engine receiving attention without being detached from its bed.—H. Reed, No. 15, 1909.



The Metropolitan Machinists' Co., 75, Bishopsgate Street Without, London, E.C., have sent us a copy of their catalogue, which is full of illustrations of motor cycle accessories. A copy will be sent to any reader on application.

Motor cyclists who are at all doubtful as to the working of a high-tension magneto should obtain a copy of "Motor Cycles and How to Manage Them." In the booklet are extracts from articles written in the simplest and clearest manner, which appeared in *The Motor Cycle* some four years ago.

An extremely tastefully designed calendar is to hand from the V.S. Cycle and Motor Co., 178, Great Portland Street, W., as well as their 1910 catalogue. In the latter there are several excellent illustrations of the V.S. single and twin-cylinder machines, as well as detail drawings of that most satisfactory of two-speed gears, the V.S. Copies of both calendar and catalogue will be sent to any readers of *The Motor Cycle* who make application to the above address.

NOTICE.

The Editor disclaims all legal responsibility in any way for loss of copy in the form of manuscript, drawings, or photographs submitted to him. Rejected manuscript, drawings, and photographs will only be returned provided a stamped addressed envelope is enclosed for the purpose.

J. DAVIS, Automobile Engineer, Barnsbury Grove, N., begs to inform readers that he is the inventor and sole builder of the protected double-seated sidecar, illustrated recently in *The Motor Cycle*. This sidecar, with tiller steering, is the last word in comfortable motor cycling. Particulars and prices on application.

WHY Buy a Sidecar which is unwieldy and troublesome, when you can get for nearly the same money our Homegaraged sidecar, which never requires detaching from the cycle, and is a better car altogether. Our grade B. sidecar, with one invisible joint, and when turned up horizontally, stands together with cycle in 27½ inches, and we guarantee it as rigid as any sidecar can be. Price £5 7s. 6d.; your own old sidecar converted into Homegaraged for £1 17s. 6d.—Bramson and Co., 5, Farleigh Rd., Stoke Newington, N.

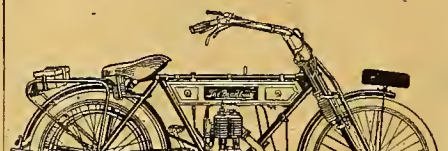
BRADBURY

3½ h.p. MOTOR.



Bradbury 3½ H.P.

An expert opinion declared it to be ahead of anything yet turned out in the Motor World.

Owing to its special frame construction, no other Motor Cycle is as rigid, as well balanced, as steady on the road, or provides the same accessibility for repairs or re-adjustment to engine parts.

3h.p., 3½h.p., new engines, £6 and £7 each; also twin, nearly new, £10.—L.H.O. Motors, Oundl

3h.p. Fafnir Engine, complete, guaranteed in good c —Particulars, 71, Avarn Rd., Mitcham Rd., Too

3½h.p. De Dion Engine, water-cooled head, with buretter, £4; plain coil, 5s.—Hart, 31, Vaag St., Deptford.

N.S.U., 3½h.p., accumulator ignition, and carbure splendid condition; £5.—Hann, Raleigh L Gowlett Rd., Peckham Rye.

3½h.p. M.M.C. Engine, B. and B. carburetter, ad 3/4 able pulley, all in perfect order; £4 10s.—S builder, Broughton, Preston.

3½h.p. Twin Peugeot, with carburetter, as new, tact breaker, and spares, adjustable pulley; or near offer.—B., 49, Durlston Rd., Kingston-on-Th

5h.p. Alcyon Engine, twin, A.I.V., new pistons fi £5, or offer; also new 25 ampere Singer acc lator, 10s.—Brown, 2, Siebert Rd., Westcombe Park

WANTED, good motor cycle; exchange modern p forte, in first-class condition, cash adjustm London.—No. L1,381, *The Motor Cycle* Offices, 20, T St., E.C.

FOR Aeronautics.—Model practical petrol mo Model practical petrol motors! Water or cooled, ½h.p., machined sets, 9s. 9d.; many sizes. 10h.p.; list 4d.—Madison Aerial Co., Littleover, D

IGNITION APPLIANCES.

L. P. and R., trembler, brand new; 13s.—Harris Newby Terrace, Bangor, Wales.

GNETO, Coil, and Accumulator repairs in two days; guaranteed; low prices.—Fellows, 49, Hert- St., Mayfair.

BRON, Registered 291-289, vastly superior to platinum, cures misfiring; best contacts for blades, rockers, magnetos, coils. Jebron has no equal.

BRON, 2s. 6d. each, rivet fitted; Jebron trimmers, 9d.; Jebron screws fit Bosch magnetos DA2, DAV, t breakers 5s. 5b. 5c. 5s. 6d. pair; old screws Jeb- d. 2s. 6d. each. Over 10,000 fitted. Try it.

BRON, fitted return post free.—From the inventor, Jebron, 38, Herbert Rd., Plumstead.

BRON Contacts were used by Messrs. Collier Bros., Colver, and Martin, in making their recent world's

DIUM Champion Contacts. — Any parts fitted returned same day. 1s. 3d. each, warranted pure, iridium trimmers, 9d.; magneto screws refitted 1. each.—Williams, 16, Wellington St., Woolwich.

BEERS Patent Cycle Petrol Economisers have proved themselves successful beyond doubt; testi- ials received state they reduce petrol consumption, ower, flexibility, save pedalling up hills. Special for one month only to enable cyclists to try it. .—Petrol Economisers, Ltd., 92, Avenue Chambers, ampton Row, London.

TYRES.

TREADING with rubber studs, 12s. 6d.; new studded covers, 21s.; why pay more?—Fox, Suffolk Birmingham.

CHELIN Cover, 26 by 2½, 17s. 6d.; Palmer, 28 by 2½, 21s.; both beaded, new.—P. Mumford, Eden Kingston-on-Thames.

STONE for Covers and Tubes; see last week's advertisement.—215 and 217, Pentonville Rd. 's Cross, London, N.

YER, Continental, 26 by 2½, beaded, 22s. 6d.; Continental Model de Course, 26 by 2, 28s.; both new. 4, Stratford Rd., Birmingham.

W 26 by 2½ R.O.M. Steel and Rubber Tyre, will not fit rim; money returned if not satisfied; 35s.— 47, Walnut St., Southport.

LIFAX.—Tyres, Motor Cycle Covers, all sizes, from 12s. 9d.; tubes, with valves, 4s. 11d. — Exchange Westgate, Halifax.

W Clincher A Won Covers, 26in. by 2¼in., 17s 6d. each; Stuart lock-joint inner tubes, 6s. 6d. —Murray, 37a, Charles St., Hatton Garden, Holborn

E'S Tyre Exchange!—Exchange that old cover for a new one and cash difference; liberal allowances; ake supplied. Try us.—69, Leather Lane, Holborn n.

MER Cord Cover, 26 by 2½, not punctured, fitted with Grose steel studded leather band, brand new; nation cost 68s., what offers?—James, dentist, Chip- m.

CHELIN Covers, brand new, carrying makers' guarantee, thick treads, 26 by 2, wired, 14s. each; 26 wired, 15s. 6d. each; 26 by 2, beaded, 15s. 6d. 26 by 2½, beaded, 17s. each.—Stewart, 12, Market forsham, Sussex.

BUSINESSES AND PROPERTY FOR SALE, TO BE LET, OR WANTED.

TABLISHED Cycle, Motor, and Side-line business for sale; important market town (South), main road entrance; turnover £800; stock about £250. 3,646 *Motor Cycle* Offices, Coventry.

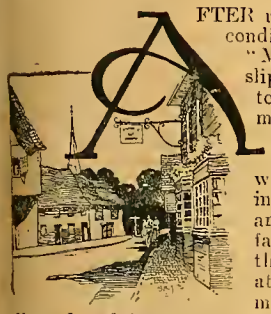
THE MOTOR CYCLE SUPPLEMENT

A.C.U. QUARTERLY RELIABILITY TRIAL.

JUDGES' REPORT.



AFTER referring to the weather and riding conditions generally, the judges report: "Many were the victims of side-slips, and though no serious injuries to the riders were reported, several machines were rendered useless, and the competitors forced to retire. At the bottom of Dashwood Hill, where the competitors, in the interests of public safety, are usually stopped, the road surface was so treacherous that after the first few riders had fallen in attempting to remount, the remainder of the competitors were allowed a flying start. This alteration of the rules naturally gave some an advantage over others, and therefore times taken to ascend Dashwood were not strictly taken into account, as those that were stopped at the bottom were forced to make three or four attempts to climb the hill; whilst the remainder, having a flying start, ascended easily. In view of this fact, stops on Dashwood are not taken into account. It was particularly noticeable that machines which were fitted with steel-studded tyres failed hopelessly on the icy surface, and there is no doubt that the trial under notice will seriously affect the use of the steel-studded cover. On vehicles with four road wheels these covers are of great service in preventing side-slips and skidding, but it would appear that on motor bicycles rubber-studded tyres are far safer, and answer all purposes, for it is often noticed that even under certain conditions in dry weather steel-studded tyres slip abominably.

"There were sixty-six entries in the non-passenger class, sixty-five being bicycles and one a tricycle, and of these three were non-starters. Thirty machines were fitted with twin-cylinder engines, of which thirteen were lightweights and seventeen heavies; whilst there were thirty-two single-cylinder machines, one only being a lightweight, and one a tricycle. Fifteen non-stop runs were claimed, nine by twin-cylinder and six by single-cylinder machines, but in several cases traffic stops which do not count against the rider were reported. Thirty-eight competitors made one or more stoppages, the causes of which can be seen on reference to the tabular report [See *The Motor Cycle* of February 7th, pages 97-8.—Ed.], whilst ten retired—six through side-slips and the remainder from various other causes. It is interesting to note that the two-stroke engines acquitted themselves very creditably; but another comparatively new type, the James machines, again failed. The Indian made its first appearance in a Quarterly Trial, and of the four machines entered three made non-stop runs, whilst the fourth only failed through an accident over which the driver had little control.

"The F.N. tricycle made a creditable performance, and had the magneto been protected the machine would have made a non-stop run. For such a low-powered engine, it climbed the hills well, when assisted by easy pedalling.

"The Ariel failed on both hills through a slipping belt, and it would appear that the spiral spring which is relied upon to press the outer flange of the pulley against the belt is insufficient to prevent the belt slipping, and in future models some means must be adopted to take up the slack of the belt when reducing the gear.

"Clutches and multi-speed gears proved of inestimable value in every way, and even expert riders of the fixed engine type were heard to express their appreciation of free engines. Now that one or two firms with big outputs have led the way in fitting free engine clutches, the present season should see the example extensively followed.

"There is no question as to the utility of the free engine clutch, whether in the hub or on the engine shaft, and given a fairly powerful and flexible engine, for general purposes of solo riding a multi-speed gear is hardly necessary.

"In the passenger class the entries numbered eight, all of which started, but, strange to say, not one non-stop run was recorded. The A.C. tricars performed badly; two overturned through side-slipping on the treacherous road surface, and the third retired from an unknown cause. The five machines fitted with sidecars made a brave show, and had not one had a slight magneto failure, all would have come through successfully. The record entry of seventy-four machines is very gratifying to the committee, for it tends to prove that the present system of marking, which was inaugurated last year, is appreciated by the trade and private riders alike, and is far in advance of the procedure of some two years ago. The marks awarded have been revised for the present season, more headings have been made, and, in consequence, the work of the judges has been greatly increased. They tender their thanks to the many marshals and observers, without whose assistance this report and the tabular one of last week could not have been issued, and they trust to receive similar assistance in future trials.—J. W. G. Brooker, H. Gillard Cove, Archibald Sharp."

AUTO CYCLE UNION NOTES.

A number of new members were elected at a recent committee meeting of the A.C.U.

The A.C.U. has now decided to consider applications for the posts of handicappers from those qualified to make applications. Each application will be judged on its individual merits.

To the list of entries for the Tourist Trophy which appeared in our issue of the 7th inst. must be added three Dot machines entered by H. Reed. The total number of entries now reaches twenty-nine.

At a recent Competitions Committee of the A.C.U. definite instructions were given to the judges to award marks to those machines competing in the Quarterly Trials for excellence of design. The judges, however, have found it quite impracticable to carry out these instructions, and, in consequence, in future the column of marks under this heading will not be included. To the list of marks published in the *R.A.C. Journal*, the words "subject to confirmation" were accidentally omitted. These marks have yet to be confirmed.

In last week's issue it was stated that H. G. Bell's F.N. tricycle was the first to complete the Uxbridge to Banbury and back course in the A.C.U. Quarterly Trial, but Dr. Stephen G. Longworth reminds us that he competed in the October combined Quarterly and Consumption Trials of 1906 on a 3 h.p. two-speed Rex tricycle, completing the distance with only one stop, due to a misfiring trouble.

CLUB

Cambridge University M.C.C.

Next Saturday the club run is to Clare. On March 5th a competition will be held, details to be announced later.

Proposed Club for St. Helens (Lancs.)

A meeting of all motor cycle and motor car owners in St. Helen's, Lancs. has been called for to-morrow (Tuesday), the intention being, if possible, to start an association.

Batley and District M.C.C.

This club has now been successfully launched, and already twenty members are enrolled, and, what is more tangible, have paid their subscriptions.

Streatham and District M.C.C.

There will be an introductory run to Godstone on Saturday next, the 19th inst., at 3 p.m. Tea and concert at Godstone 5 p.m. In a week or two Mr. A. E. Bennett has promised a lecture on "Magnetos."

A Motor Cycle Club for Doncaster and District.

A number of motor cyclists in Doncaster are anxious to form a club, and we are asked by Mr. George F. Stafford, of 7, Baxter Gate, to state that he will be very pleased to receive the names and addresses of local readers interested in this project. A meeting will then be arranged, rules drawn up, and officers elected.

Liverpool M.C.

On Thursday last a club supper was held at headquarters. Next Thursday an inter-club billiard match has been arranged between Manchester Motor Club and Liverpool Motor Club, consisting of four players aside, first game at Manchester headquarters, starting 7 p.m. On Friday, 25th inst., members of the above club will visit the Manchester Motor Show. Train leaves Central Station 5 p.m., or meet at show.

The "breakdown" competition referred to last week proved very interesting. Mr. Fehr, who deranged the Premier motor cycle lent by Messrs. Owens, had carefully cut the wire leading from the high-tension terminal on the magneto to the sparking plug, so that a shortage of the current took place, and of the competitors only one—Mr. S. W. Carty—located the trouble in the five minutes' time limit, he therefore being adjudged the winner.

Glasgow M.C.C.

Prizes won during 1909 were presented at a smoking concert held at the Landsdowne Restaurant, Hope Street, Glasgow, on the 3rd inst. An excellent musical programme was provided by Messrs. Hood, Deans, Kirkpatrick, Jack Collins, Finlay Brown, and others, and during the evening a gold watch was presented to Mr. J. S. Fulton. In introducing the matter, Mr. H. S. Bilbe, in a humorous speech, accused Mr. Fulton of having spoilt the members during his four years' term of office by doing work that should rightly have been performed by others, and now that he had relinquished the post of secretary it was not always easy to find members ready to do what was necessary. Mr. Hutchison, one of the original members of the club, in an excellent speech, asked the late secretary to accept the presentation as a mark of appreciation from the club. Mr. Fulton's speech in reply dealt with the early days of motor cycling, when he and Mr. Hutchison had ridden 2 h.p. Clément-Garrard machines. He stated that the Glasgow M.C.C. was the pioneer motor cycle club of Scotland, dating back to 1902, and urged the members to keep it always in the lead. The chair was taken by Mr. D. S. Baddeley.

Stockport and District M.C.C.

The A.G.M. was held at the new headquarters, White Lion Hotel. Some thirty members were present. The hon. secretary's report was most favourable. The number of members on the books at the close of last year was forty-five. The treasurer's balance sheet showed a fair balance in hand.

Coventry and Warwickshire M.C.

The sixth annual dinner and presentation of prizes took place on Friday evening last in St. Mary's Hall, Coventry.

St. Mary's Hall is a building which has seen many royal functions, but it is the first time a motor club banquet has been held within its walls, which are hung with tapestry representing some of the more important scenes in the history of the city, and contains also several suits of ancient armour.

Upwards of ninety members and friends assembled round the three tastefully-arranged tables under the chairmanship of the retiring president, Colonel Wyley, V.D., who was supported by his Worship the Mayor of Coventry (Ald. Wm. Lee), Messrs. J. E. Swindlehurst (City Engineer), John V. Pugh, E. M. Iliffe, M. J. Schulte, H. W. Stauer, etc. The vice-chairs were occupied by Messrs. E. J. Hardy, V. A. Holroyd, and V. Riley.

After the Royal toast, proposed by the Chairman, the Mayor proposed "The Club," and gave a brief *résumé* of its work during the past year; he particularly referred to the able manner in which Col. Wyley had filled the post of president since the inauguration of the club six years ago, and asked him to accept a handsome inkstand as a small appreciation of his services. The retiring hon. treasurer, Mr. E. J. Hardy, was also the recipient of a solid silver salver, suitably inscribed.

Colonel Wyley, responding, thanked the club, and referred to the growth of the membership, which had now reached 150. He suggested that this year's Military Reconnaissance should consist of an attack on

Burnley Victoria Cycle and M.C.

Motor cyclists in Burnley and district who would like to join a club are asked to communicate with Mr. E. Brown, hon. secretary of the Burnley Victoria Motor Club, Myrtle Cottage, Burnley, or attend a special meeting to be held at the Central Commercial Hotel, St. James's Row, Burnley, on Wednesday next, the 16th inst., at 7.45 p.m.

Nottingham and District M.C.C.

At the recent A.G.M. the report was adopted, and the balance-sheet and accounts (which showed a small balance in hand) passed. Lord Henry Bentinck is to be invited to act as president this year. The 1909 committee was re-elected *en bloc*. A discussion ensued as to the advisability of continuing affiliation with the A.C.U., and the committee was instructed to recommence action at the end of six months.

Harrogate and District M.C.C.

An instructive paper was read on Thursday evening last by Mr. F. C. Bagshaw, entitled "Preparations for the Tourist Trophy Race." The lecturer dealt with his subject very thoroughly, and at the conclusion he was heartily thanked for his very able paper.

Will members please note that next Saturday the carnival takes place?

Friday evening last in St. Mary's Hall, Coventry.

Walthamstow M.C.

The business of the A.G.M. not being completed at the last sitting, it was adjourned to Wednesday next, when it is hoped that members will make it convenient to attend at headquarters at 8 p.m. to complete the agenda

Bishop Auckland, Darlington and District M.C.

At the recent annual general meeting of the above club, presided over by Mr. T. W. Craig (chairman), the reports of the secretary and treasurer, which showed the very satisfactory progress the club had made since its formation in July, 1909, and the favourable condition of its finances, were adopted. The membership of the club now totals ninety-four.

Western District M.C. (London).

The following items of general interest took place at the last committee meeting. The committee, after hearing the result of the chairman's interview with the secretary of the A.C.U., decided to continue the affiliation for the present year. The fixture list was entrusted to Messrs. Vowler, Hughes, and Babbage, and it is hoped that it will be ready in a few days. These gentlemen were instructed to fix up competitions for the first Sunday in each month. The Winter and Smart cups will be competed for as previously, and the Triumph Cup will be run for to Daventry.

Middlesbrough and District M.C.C.

Last Wednesday evening Mr. W. A. Macgregor delivered a lecture entitled "Oils and Lubrication." As fully seventy-five per cent. of those present joined in the discussion which followed the paper, there is no doubt that it was thoroughly appreciated. Mr. J. Bellerby (chairman of committee) occupied the chair.

A letter that had been sent to the secretary by Mr. George R. Sanderson (one of the founders, and hon. treasurer and financial secretary of the club) resigning his position as hon. treasurer was read during the evening. Mr. Sanderson is leaving the district. Many expressions of regret were made at the loss of so enthusiastic an officer, and the letter was left to the committee to answer in suitable manner. Mr. J. G. Fairgrieve was elected to the office of hon. treasurer.

Northamptonshire M.C.C.

Mr. D. C. M. Hume treated the members of the N.M.C.C. to a brilliant and original lecture on "Magneto Ignition" on February 8th, the interest he had excited being shown by volleys of questions at the conclusion of the paper. He did not avoid deep technicalities, but the excellent slides made specially for the occasion enabled even the novices present to grasp his drift. Some of his matter represented entirely original experiments concluded within the last week or two. He showed a slide of Prof. Fleming's table of the voltages required to leap spark gaps of varying widths; it was interesting to notice that 30,000 volts are required to give a spark across a gap of 20 mm. In addition, he showed slides depicting electrical processes in the magneto in curve form, including the potential differences in the primary circuit, and the voltage at varying engine speeds with the spark retarded, half advanced, and fully advanced. Exhibits illustrating the complete range of Simms specialities crowned the interest of a most instructive evening.

Newcastle M.C.

The annual meeting was held in the County Hotel, Newcastle, last Wednesday, Mr. Arthur J. Lucas presiding. The annual report, presented by Mr. Robson, the secretary, recorded the successes of one of the busiest years in the annals of the club, and was unanimously adopted. The auditor's report on the secretary's accounts, which showed a balance in hand of £11, was received.

Mr. Alan Robson (secretary) moved: "That the affairs of this club be wound up, and its membership be transferred direct to the North-eastern Automobile Association." The motion met with some opposition.

Mr. Dunn suggested that all the clubs in the North should amalgamate, and seek to secure an equal and just absorption of all the clubs. Their funds were good, and he knew of three gentlemen who were prepared, if need be, to put down £20 to carry on the club.

An amendment moved by Mr. J. Daglish, calling for a more complete scheme, pending which the form of the club should not be changed, was carried by a large majority.

MOTOR CYCLING CLUB: FORTHCOMING EVENTS.

The Jarrott Cup Competition.

THE rules and regulations governing the M.C.C.'s London to Land's End and back run, at Easter, for the Jarrott Cup will be circulated among members within the next few days, and potential participants should make a note of the dates, March 26th and 28th.

In order to make the run more attractive, competitors' machines will not be locked up during the Sunday, the intervening day between the outward and homeward journeys, so that entrants will be able to take rides to interesting places near Penzance, and there are many. Members who are keen on long rides of this nature, free from harassing restrictions, should not miss this classic ride. The road conditions and scenery are particularly varied, albeit interesting, and those who have never done the journey have missed a real treat. The trials hon. sec. for this event is Mr. E. Gwynne, White Lodge, Credition Road, Hampstead, N.W.

London-Edinburgh Run.

Mr. Harry G. Bell is again acting as trials hon. secretary for this run, which increases in popularity every year, and has already started to work. The rules and regulations will reach members shortly, and there will be several new features to add to the attractiveness of this event. As proof of the popularity and keenness of riders in this run, it is sufficient to state that Mr. Bell has already received numerous enquiries for particulars, one being from a good friend of the club, who has acted as checker for several years past. He wants to take a still more active part in the run this year by competing.

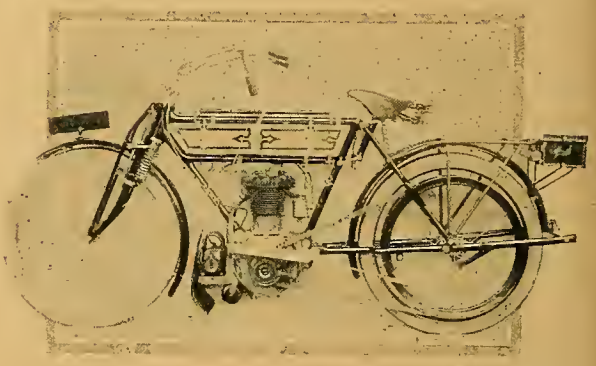
The Opening Run to Brighton.

The opening run to Brighton, fixed for March 12th, will commence the year's fixtures on the road. Mr. E. B. Dickson, the popular captain of the club, has the arrangements in hand.

THE 3½ h.p. SWIFT-ARIEL.

THE Swift Cycle Co., Ltd., are now selling an exceedingly well-made motor bicycle known as the Swift-Ariel, entirely handled by the Swift Cycle Co.'s London depot, 15-16, Holborn Viaduct, E.C., whither all enquiries should be addressed.

In the 3½ h.p. Swift-Ariel all details have been carefully considered. The workmanship is of the best, and the machine is one which should strongly appeal to the British public. The engine is of 3½ h.p. (85 by 85 mm.) with mechanically operated valves situated side by side. The ignition is by chain-driven magneto, while the chain is protected in an aluminium case. The transmission is by means of a ⅞in. rubber belt of the best quality, while on the engine pulley is fitted a patent variable gear with adjustable pulley, free engine and starting handle, controlled by a lever situated on the left handle-bar, which expands and contracts the pulley flanges, and gives ratios varying from 1 to 4 to 1 to 5. On each side of the engine are aluminium footrests, through which rubber studs project, thus affording a comfortable position for the rider's feet, and, at the same time, absorbing much of the vibration. The engine is supplied with gas by means of a Brown and Barlow handle-bar controlled carburetter. The spring forks are the well-known Druid, which allow a front rim brake to be fitted. Not only are the forks sprung, but also the seat-pillar, which is suspended at the rear of the seat tube and connected to it by double rocking levers and two suspension springs. A recoil spring is also provided. The details of the machine are particularly well thought out. For example, a generator clip is fitted to the right hand side of the fork crown, the wide and efficient mudguards are held down by bolts provided with rubber buffers, while a Reflex road light, which reflects a red rear light, is supplied with every machine. In addition to these, the outfit of tools is not only of the best quality but most complete. An efficient stand is fixed to the rear fork ends, while a strong tubular carrier, provided with a tube holding the lubricator and paraffin oil cans, is also supplied. We have no doubt that the Swift-Ariel will rapidly create a big demand among motor cycle connoisseurs.



The 3½ h.p. 85×85 mm. Swift-Ariel motor bicycle referred to in the accompanying matter.

FATAL ACCIDENT TO A MOTOR CYCLIST.

On Wednesday last at Stromford Bridge, near Tittensor, a most unfortunate collision occurred between a motor cyclist named Bertram Hodder, of Stone, and a car owned by the Duke of Westminster, which was driven by George Powell. The car was proceeding from Eaton Hall to Belvoir Castle, whilst the motor cyclist was riding to his place of business in the direction of Newcastle. The occupants of the car said that they saw the motor cyclist approaching, and all of a sudden he went across the road in front of the car. [A local rider sends us his views of the occurrence, and considers that most likely the motor cyclist turned into the gutter in order to pass, and, owing to the mud, skidded in front of the car. —Ed.] The motor cyclist's head seemed to have struck the centre of the forepart of the car, resulting in terrible injuries. The unfortunate man was removed to the North Staffordshire Infirmary, where he died immediately on arrival.

THE NEW TAXATION SCHEME.

We have received a letter from a Sussex reader asking us to urge one of the motoring organisations to take up the motor cyclists' case in order to bring about some remedy to the obvious injustice of the present proposed motor cycle taxation before the Budget passes into law. The election is over and the Budget will shortly be reconsidered. His chief grumble seems to be the injustice of taxing a lightweight motor-assisted bicycle just the same fee as a 9 h.p. motor bicycle with a sidecar attachment. He suggests that a 15s. licence for motor bicycles up to 5 h.p. with an increase of 2s. 6d. for each h.p. over 5 h.p. would be much fairer. We quite agree, but, unfortunately, we cannot hold out much hope that our correspondent's views will be accepted by the powers that be at this stage. The A.C.U. and M.U. have already urged the motor cyclists' case before the Chancellor of the Exchequer, and everything has apparently been done by these bodies to prevent the increase of the 15s. tax without effect. The riders of lightweight machines must, we fear, pay for the present on the same basis as for heavier and more powerful machines.

Road Surfaces.

IF there is one thing more than another which is brought closely before motor cyclists at this time of the year it is the extreme contrast between the surfaces of roads which are or are not treated with one or other of the modern compounds used as top dressing on main roads. Some which are used for dust laying seem to be quite as effective in preventing mud, and it is to these we refer particularly.

In the winter time, when most roads are covered with mud in various stages of wet, dry and drying, to suddenly leave a surface on which one has some difficulty in steering a straight course, and to arrive on half a mile or a mile of perfect waterproofed surface due to proper road treatment, makes one wonder why it should not be possible to treat all main roads in a way which would render them suitable for modern traffic despite the weather conditions.

Surely it must be more economical in the long run to provide a surface which does not require the mud removed from it at intervals, and which also does not appear to require the constant repairing which is necessary with a macadam surface. In our opinion, if the whole of the motoring organisations were to join hands and agitate for all main roads to be specially treated in such a way that they would resist rain and not work up into a pasty compound on which it is a misery to ride, they would assist all classes of motorists far more than anything else they could possibly do in the way of forwarding the motoring movement. Although it is possible to ride a motor bicycle on the muddiest roads, the pastime would be made far more delightful if one could always be sure of at least a moderately smooth and dry surface at any time during the winter months. That it is possible there is ample proof, and all road users would welcome the more general adoption of a waterproofed road surface.

Official Recognition of Records.

EVER since *The Motor Cycle* compiled the first complete list of motor cycle records, we have felt that the duty is one which should be undertaken by the governing body in each country. Records made at home are at present verified and sanctioned by the Auto Cycle Union, but as regards foreign records no official list is kept by the A.C.U., so far as we are aware; at any rate, no official list is circulated. This places us in an awkward position regarding American records, as we are left to accept or reject a record as we think fit. We take each claim on its merits, and in the absence of official measurements and the usual verifications we are in a quandary as to whether the record should be recognised. This state of affairs is not as it should be, and it is high time the A.C.U. extended its sphere of usefulness by taking note of all foreign records which are properly authenticated and keeping a Blue Book. On this same subject a letter appears in our correspondence pages from Dr. J. P. Thornley, chairman of the Federation of American Motor Cyclists, suggesting that the Auto Cycle Union appoint a committee to confer with the F.A.M. once a year, and issue a list of world's records for the preceding year. We would strongly urge the British governing body to adopt the suggestion, and so put an end to the prevailing suspicion concerning American records in general. The benefits that would accrue to manufacturers by reliable comparisons of speeds attained at home and abroad from given cubical capacities would be of inestimable value.

1200 MILES ON A MOTOR BICYCLE WITH SIDECAR

BY

VINCENT BURROW, M.D.

IT has always been my desire since becoming a motor cyclist in 1902 to plan out and undertake a tour once a year. I have usually managed to accomplish this with fair success. Riding solus, however, appealed to me less and less, and I hailed with delight the advent of the trailer, forecar attachment, and latterly the sidecar, all three of which I have tried, and have discarded the two former in preference for the more sociable sidecar attachment.

Accordingly, last year my wife and I decided upon a tour from the bleak coast of Northumberland to Devonshire. We could only manage a fortnight, so decided to allow a week for travelling, the remaining seven days to be devoted to seeing some of the beauty spots of Devon at our leisure.

And now a few words as to our machine and equipment. Profiting by former experience, and by the advice given and repeated *ad nauseam* in *The Motor Cycle*, that a passenger machine must have plenty of power and be provided with a two-speed and free engine device, I decided on a 6 h.p. twin-cylinder N.S.U., with N.S.U. two-speed and free engine pulley, Bosch magneto, 1in. Continental belt, and Peter Union tyres. The sidecar is a Montgomery, flexible pattern.

As to Luggage Carried.

There is a large wicker luncheon basket under seat of sidecar, which we packed to overflowing with luggage, not forgetting a few spare parts for the motor. We also made a large hold-all of American cloth, packed this, and stowed it under the seat between the latter and the luncheon basket, securing it with straps. During the tour we found this rather a nuisance to attach or take off, and another time should remove the wicker basket altogether and strap in its place a fair-sized Japanese basket, which is much handier, and would serve well, if properly lined. Besides the above, a fair-sized basket, containing kettle, pans, spirit stove, provisions, etc., for picnicking on the road, was set in the front of the sidecar at the passenger's feet.

The Route.

We arranged to go down by the western route and return by the Exeter to London road, striking north at Andover, and getting on the Great North Road *viâ* Oxford and Northampton at Stamford.

FIRST DAY.—Newbiggin to Hexham, 54 miles.

Leaving Newbiggin at 5 p.m. on September 7th in good weather, we drove *viâ* Gosforth and Heddon-on-the-Wall to Hexham, arriving there about dusk. The ride was uneventful, except that the engine for the first twenty miles was frequently misfiring, and there was some slipping of the high gear clutch on some of the hills. The route is very hilly, and the road rough; this follows the line of the old Picts' wall.

Hexham is situated in a very picturesque part of the county. Buildings of note are a very fine old abbey and, in contrast, a modern hydro.

SECOND DAY.—Hexham to Tarporley, 155 miles.

After partaking of a light breakfast of tea and bread and butter, we left Hexham at 7.45 a.m., after having replenished the petrol tank, and soon arrived at Haltwhistle, where one of the two steep hills between Newcastle and Carlisle is encountered. Here the gradient, which is about 1 in 8, necessitated the use of the low gear and slight pedalling. The other hill, equally steep, is Greenhead, which we negotiated successfully on the low gear. The morning was up to now thick and misty, but this gradually cleared as we neared Brampton, and for the rest of the day was clear and bright.

Proceeding, with the twin-cylinder gently purring, and the high gear no longer slipping, we entered Carlisle about 10 a.m., and threaded our way amongst the streets of that city.

Two miles south of Carlisle, we drew up by the roadside, and, having obtained some fresh milk at a farm,

Showing the country within the range of a motor cyclist in less than a fortnight. See Dr. Vincent Burrow's article.

1200 Miles on a Motor Bicycle with Sidecar.—

we took out our lunch basket, the kettle was soon boiling, and we made a hearty breakfast. The sun was now beginning to exert its power, and after the N.E. coast, we found it very hot. After washing up and repacking, we proceeded on our way, filling up with

Tyneda'e, Hexham.

petrol at Penrith. We passed through Shap, and took Shap Fell well on top gear, except for about 150 yards near the summit, which required the low gear, when the motor made such short work of it that I tried the high gear again, on which we breasted the summit. On the other side we coasted down for some miles with engine free, saving our oil and petrol.

Passing through Kendal, we had an uneventful run *viâ* Lancaster to Preston, where I obtained a gallon of petrol at an exorbitant price. On enquiring the way to Wigan, no one seemed to have any idea that there was a town of that name within 100 miles. We were finally directed to Chorley, which appears to be a large colliery or manufacturing town. Having gone several miles, we at last came upon a sign-board, when, alas! we found we were making direct for Blackburn. Calling to our aid a friendly policeman, we were given instructions which enabled us to get on the Chorley Road, across country. About one mile from Chorley is the turning to Wigan—a sharp turn on the right. About this spot we had tea on the roadside.

Wending along Wigan Tramlines.

Entering Wigan, we wended our way along the many miles of tramlines and stone setts towards Warrington. This part of the route is very bad, the jolting is atrocious, the surface is horrible, and on a wet day motor bicycling here would ensure a succession of skids. To add to all this, there are no sign-boards of any description. As Warrington is approached the road, however, improves.

From Warrington to Tarporley the road is good, and we were making good time when the back tyre went flat, just as it was getting dark. Not having jointed tubes, I had to light up, when I found a nail sticking through cover and tube. I looked carefully to see whether the nail had made two holes in the tube, but could only detect one, so contented myself with mending the visible puncture, and pumped up. The evening proved very dark, and to make things worse, my gas lamp would not burn well, so that I had to drive slowly, and it was 8.30 when we arrived at Tarporley. We put up at this old world town, and were quite ready for our supper. That evening we found, as obtained every evening after motoring any distance, that as soon as we had finished supper, we could not keep awake, and were always ready for bed immediately we had finished eating. I must recommend motoring for insomnia.

THIRD DAY. — Tarporley to Stroud, 130 miles.

After the usual light breakfast about 7.15 a.m., I went to get the motor out when, alas! I found the rear tyre flat. I thought it would save time to get a repairer to see to it; it proved a vain thought. The repairer arrived half asleep, and I looked anxiously at him, but failed to see any signs of levers, solution, patches, etc. It sufficed that he had brought himself upon the scene. With exasperating and slothful torpidity he hazarded to take off the cover, after walking round the machine and eyeing it suspiciously. It was, as I suspected, a second puncture caused by the nail I had picked up the day before, and which I had not discovered in the dark the previous evening. My repairer calmly suggested that, unless I provided him with solution, patches, chalk, etc., he would have to return home for his. Exasperated, I thrust my repair outfit into his hands and set to work myself also, and, whilst waiting for the cover to be replaced,

Shap Wells Hotel, Penrith.

1200 Miles on a Motor Bicycle with Sidecar.-

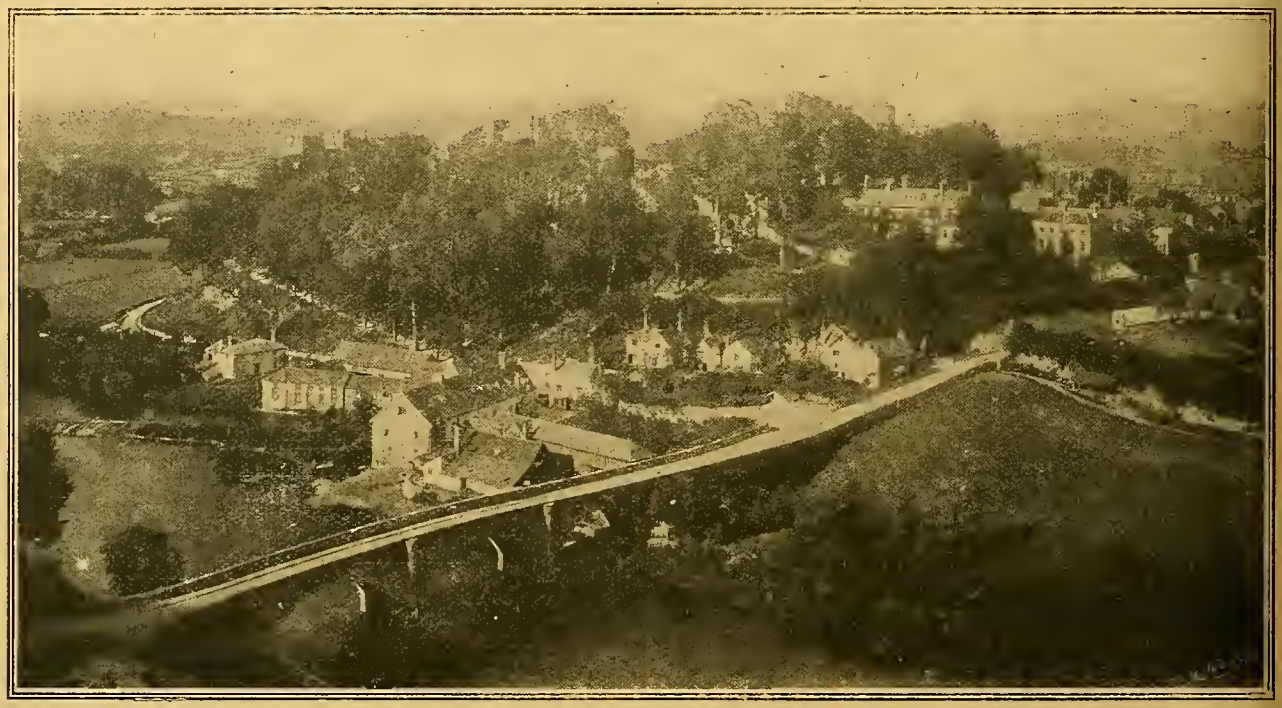
oiled the magneto and wheel spindles. Eventually, we were at last ready and attempted to start, but had only gone a few dozen yards when we encountered a dozen or so of horses (hunters) returning from their morning exercise. They objected to the throb of the engine, and had to be coaxed into a side lane before we could proceed. The weather was again magnificent, and we had an enjoyable run to Whitchurch, thence onward towards Shrewsbury, when we found the horn refused to utter its usual warning note. My passenger attempted to clean the reed whilst we were going along, but unluckily bent it. I spent upwards of half an hour trying to adjust that reed, and to anyone who attempts a similar adjustment on the road I would give this one word of advice—"don't."

In Shrewsbury I obtained a new reed and some petrol, and, having noticed my Continental belt rather the worse for wear, the rubber having worn off one side, I spent upwards of an hour trying to get another, but could get no belt there of any description. Shrewsbury is very hilly, but is a nice clean city.

Usefulness of a Spare Piece of Belt.

Passing over the bridge on the south side, we again got on our way, and, halting a short time for breakfast, picnic fashion, afterwards were soon passing through Church Stretton. We encountered a long hill between the latter town and Ludlow, close to which town the belt broke. Inwardly thanking the N.S.U. people for including a spare half foot of belt with the tool outfit, I pieced the belt, in the broiling sun. We encountered another long hill between Ludlow and Hereford, taking some more petrol at Leominster. The machine took both hills on top gear. In the afternoon we ran into Hereford, where I got a new Gloria belt. This I carried with me, and the old belt took us to Exeter previous to my discarding it.

We spent an hour in Hereford, and had tea there. Thence we ran on to Ross, hoping to see something of the beautiful Wye Valley, but were disappointed, as to see this it is necessary to go on to Monmouth, instead of which we drove on to Gloucester, passing over some very mountainous country necessitating much low gear work. Passing through Gloucester, we found the place decorated with flags and bunting and very congested—it was the Gloucester Annual Festival. We did not delay, however, and were soon climbing the formidable hills *en route* for Stroud; the low gear was again required, and on the worst part of the gradient we were forced to run on to the grass to avoid a long line of brewers' drays drawn across the road.



Castle Hill and Dinham Bridge, Ludlow.

After passing them and arriving on the top of the hill, from which we got a magnificent view, I took out ¾in. from the hard-worked and stretched belt.

At 6.30 p.m. we entered Stroud, which is built on the side of a veritable mountain, and, not knowing the town, we ran straight up on the low gear, when we found we had overshot the main street and had to descend again. The gradient is certainly not less than 1 in 10.

On this day I discovered why my lamp had burnt so badly the previous evening. There was a small pin hole in the rubber tube leading from the generator. Luckily this was near the lamp, and allowed me length enough to cut out the defective portion.

FOURTH DAY.—Stroud to Bath and Exeter, 120 miles.

The weather was magnificent when we left at eight o'clock. There was a stiff hill to climb out of Nailsworth (where pins are made), but on reaching the summit we got a splendid view of the beautiful Stroud Valley.

We found the roads bad and much cut up by farm carts as far as Cross Hands. We climbed a long hill

1200 Miles on a Motor Bicycle with Sidecar.—

near Cold Ashton, and then had a "free engine" run for three miles to Bath, arriving there at 9.45.

We stayed an hour, and on leaving essayed to climb the long but gentle gradient out of the city. The tram lines and road were wet and greasy, and here we had a startling experience. Fortunately, I had put the engine on the low gear, owing to the grease, when suddenly we began to skid on the treacherous oolite surface. There was a cart on one side, and coming down the centre of the road was a tramcar. We slithered broadside fashion over to the left and brought up against the kerb, the tram just missing the sidecar, which was attached to the right-hand side of the cycle, by a few millimetres. Needless to say, my passenger walked up the remainder of the hill, whilst I, by keeping my feet dangling on the ground, managed to get to the top, but not without several bad skids, but now I had the whole road to cut figures on.

Proceeding, we "freeled" down a long hill to Dunkerton, then up a veritable mountain, and down again to Radstock; again up a very steep bank to a place where we alighted for breakfast, and where I again oiled the magneto. It was now very hot again, but the heat only troubled us when we alighted and missed the rushing of the air past our rapidly moving vehicle.

Bird's eye view of Stroud from Rodborough.

The road to Wells was bad, but we got there at 1 p.m. We stopped to admire the magnificent cathedral, and entered the sacred building. The air inside was delightfully cool.

Cheddar Cliffs and Caves.

We then proceeded along the Mendip Hills to Cheddar, which is quite a summer holiday resort, and here we visited the caves. These are well worth inspecting, and the one we entered was lit up by electricity, arc light, and incandescent. These caves are in the cliff, and were formed by subterranean rivers. They were discovered in 1893 and a further series in 1898. The interiors are very beautiful; there are thousands of stalactites depending from the roof, of all sizes, and the gleam of the arc lights upon the snowy white calcareous deposits in certain places produces a wonderful and pleasing spectacle. A niche, high up in one of the inner caves, when lit up is supposed to indicate a representation of King Solomon's Temple, with the Archangel at the side. Another effect caused by the light striking the rock facing this is a representation of Niagara Falls.

Having taken our fill of these sights, we left at three in the broiling heat. I soon had to remove a piece from the belt, and, passing through Axbridge, we ran on to within a mile or so of Bridgwater, where we stopped to boil our kettle and have tea. Then we ran on to Taunton, filled up with petrol, and left at 5.45. There is a long stiff hill out of Wellington, and the road is bad. Passing through sleepy Cullompton, we made our way towards Exeter, when the belt broke near Pinhoe. One mile further on it again broke. This delayed us so much that it was half past eight when we entered the city of Exeter, and put up for the night.

All this day we were troubled with defective lubrication. I found it most difficult, and often impossible, to obtain Price's or Vacuum oils, and the substitute tendered by garages was useless, and occasionally the engine actually stopped from running dry.

FIFTH DAY.—Exeter to Cullompton, 12 miles.

Having arrived in Devonshire, we were now ready for a well earned rest from long distance touring for a few days. The motor had so far behaved very well indeed.

We spent the day in Exeter, which is a very interesting old city. After walking from the Arcade in Eastgate to the Exe Bridge, passing several very old churches on the way, we returned and went into the Guildhall. This old building, dating back to 1330 A.D., fashioned of Devon stone, was formerly used as a merchants' hall, but now is used as an assize court for the county of Exeter. The main hall is hung with portraits of former mayors, and has on the panelling the arms of all the old city guilds, most of them now extinct.

Northernhay Park is pleasant after the bustle of the streets. We also saw the remains of the old castle and city walls, within which are situated the county assize courts. In the main court is hung the famous picture entitled "Thou shalt not bear false witness," representing the trial of Susannah and the two perjurers before Daniel. It was in this court that the murderer John Lee was tried and convicted twenty years ago. We were shown the cell in which he was placed. Some will remember that two attempts were made to hang him, but the trap failed to drop, and his sentence was commuted to penal servitude for life. I believe he was released last year, and is now residing with his parents somewhere in South-west England.

Calling for our motor, we left Exeter early in the evening, and arrived at Cullompton about six o'clock. Near this town we spent the next two days, basking in the sunshine, in glorious ease, feasting on cream and drinking delicious cider. The motor was used to take friends for short spins during our stay in Devonshire.

(To be continued.)

THE QUARTERLY TRIALS.

A CRITICISM BY A.E.F.

AS a spectator at the last Quarterly Trials I was consumed with wonderment; but for a time I held my peace, thinking my inexperience in such matters had made me ultra-critical, and that perhaps all motor cycle competitions were conducted in the same haphazard fashion. A chorus of complaints from more expert quarters has now inspired me to speak freely of what I saw and heard. As an enthusiastic rider myself, I thought the officials had bitten off rather more than they could chew in aspiring to check seventy-five riders for absolute non-stops over a 125 miles course! The gentlemen responsible for this arduous job were contained in two or three motor cars, and were compelled by the exigencies of duty first to sprint ahead of the entrants, then pause an hour or more at Dashwood, then sprint madly again into Banbury, then lunch, then sprint out madly to Amersham, pause another hour or so, and finally sprint madly once more into Uxbridge. Nobody saw less of the trial than they did, except on the two timed hills.

7,000 Miles to be Officially Observed.

The entrants covered about 7,000 miles between them, and of that distance the officials cannot conceivably have "observed" more than a tenth. An impartial outsider may therefore be pardoned for asking on what evidence the alleged "non-stops" rest. On the observations of other competitors maybe—each man being jealously scrutinised by the other seventy-four? He is certainly jealously scrutinised, but only in very rare cases is he reported to the officials. Few men like the game of espionage; some few who would leap at the chance of showing up a dishonest rival may stand in similar danger themselves. I doubt if one man out of every twenty-five entrants would care to report manifest dishonesty on the part of a rival. Then each competitor's non-stop depends on his own honesty? We might depend on that if the event were a purely sporting competition, devoid of material awards, and contested solely by the highest type of sportsman, be he amateur or professional. But anyone can compete who can raise half a guinea or persuade someone else to pay it for him. In connection with this very event a certain maker wrote to a friend of mine who is an expert amateur rider, and said he would receive a better advertisement if his machine were put through by an amateur, and would he ride it? In reply my friend told me that he wrote and stated he had no intention of buying one of the machines in question, and could only ride as a "private owner" on a mount that was his personal property. The maker answered that he would be happy to send the machine along with a stamped receipt for its price, and my friend could return it at the end of the competition season! There is therefore a certain percentage of dishonesty even in these small trials, against which the honourable owners and firms ought to be protected; and *ergo*, we have no right to trust implicitly to the *bonâ fides* of the entrants, whether in ownership qualifications or in observation. Leaving all other moot points out of consideration, it was nothing more or less than a farce to award non-stops to any of the huge entry under such miserably inefficient observation as obtained on January 29th.

A RECORD FOR RELIABILITY.

Mr. T. M. Anderson, of Evesham, claims the reliability record for the above motor cycle, which was built by Mr. F. M. Lee, of Liverpool. It is on its 53,000th mile, and has not yet been in a shop for repairs. The machine is called the Waverley, and the engine is a 7 h.p. twin J.A.P.

Should the Non-stop Principle be abandoned?

We then come to the dilemma whether it is possible for the A.C.U. to perfect its observation, or whether it is necessary to abandon the "non-stop" principle altogether in trials of this character simply because of the difficulties of verification. I am bound to assert very strongly that the A.C.U. did not avail itself to the full of the facilities at its disposal. There were quite a number of car owners and motor cyclists present during a portion or the whole of the route, of whom the officials made no attempt to avail themselves. We were eyed with a sort of calm disdain by some of these gentlemen—treated as unwelcome interlopers. This is not only true of non-competing strangers, but also of men as well known in the motor cycling world as the A.C.U. officials themselves, one or two of whom when they are clad in a little brief authority forget not

The Quarterly Trials.—

only their manners, but also the responsible duties with which the motor cycling public burden them. On Dashwood Hill alone—about the handling of which climb complaints are especially rife—there were at least a dozen well-known motorists, who might have been of vast service; but here, as elsewhere, there was not even a friendly invitation to assist. As a consequence we did not push ourselves forward where we were evidently not wanted, and at Banbury we conversed amongst each other of a dozen stoppages of which the officials were totally ignorant, some of the incidents ranking against entrants now officially accredited with "non-stops," and a good sporting chance of the champion cup at the end of the year; in fact, the official award list is known to about twenty outside motorists to be a ridiculous mockery, quite apart from any information possessed by the entrants themselves, many of whom could a tale unfold, an' they would.

BOY SCOUTS, INSPECTION ON SOUTHSEA COMMON.

A capture! Boy Scouts holding up a motor cyclist and searching him for despatches.

Practical Suggestions for Improvement.

I have serious doubts whether the non-stop principle is really applicable to a large entry of motor cyclists over a long course. I know it is difficult of application to a small entry over a restricted circular course; provincial club experience has burnt that into my mind. I know it is impossible in such a trial as the last quarterly, with only two or three car loads of officials already burdened with many other arduous duties, and to attempt to maintain it under such conditions can only lead to heartburning within the Union and derision outside it. If attempts are made to prolong the system I would suggest certain practical measures, otherwise the popularity of the Trials is, in my opinion, likely to suffer.

The inquisitive scout does not stop at searching a motor cyclist. Observe the boy kneeling and searching the P. and M. motor cycle.

The man in the street has at last learned what terrific battles are fought by the Boy Scouts and the Assistance Association. The encounter took place between a party of scouts and about a dozen cars and motor cycles before Admiral Robinson last week.

The first is the limitation either of the entry or the course. An entry of twenty-five might be verified for non-stops over the present course, especially if riders were forbidden to overtake a leading car (which should be very powerful) or to fall behind a following car. An entry of seventy-five might be verified for non-stops over a shorter course, but with any staff of officials which is practicable an entry of seventy-five is not verifiable for non-stops over a 125 mile course, and the whole motor cycling public is well aware of the folly of such an attempt. The entry might therefore be limited by excising the private riders or by limiting the trade entries to one machine of each type, or, alternatively, the course might be curtailed very appreciably and converted to the "lap" type.

Secondly, if the A.C.U. retains its present system — and, knowing its ways, I suspect it will—it might at least avail itself to the full of all possible assistance. Paragraphs appealing for observers in the columns of the *R.A.C. Journal* are of little use. Some men dare not promise to assist, because their engagements are variable or because they fear bad weather; many who dare not bind themselves actually turn out on the day. There was a large muster of non-competitors out on the 29th, in spite of the awful conditions. The profits of the trial with an entry of seventy-five allow of cars and motor cycles being hired to make the observation more efficient. Southern clubs would respond if invited to make themselves responsible for particular patches of the route, especially after lunch. But I leave remedies to wiser and more experienced heads. I merely assert that the last trial was a laughable farce rather than a serious test, that the trade and the public attach precious little importance to it, and that reform is urgently demanded.

OCCASIONAL COMMENTS

BY "IXION"

Accessibility.

The cute rider never changes his make without overhauling the machine that has smitten his fancy with an eye to its accessibility. Long experience of his old mount has taught him that sundry portions are distinctly awkward to remove and replace. His first move will be to scan critically the corresponding details of the potential purchase. The cylinder, carburetter, and inlet pipes are the principal points to keep in mind. Secondly, he will carefully examine any details in which the new mount differs at all radically from the old. In particular, if he is going in for an entirely novel design, he will be specially critical in this respect. I was tremendously struck by my first inspection of a certain machine at the Stanley Show; as my dazzled gaze slowly descended to details I began to suspect that the removal or adjustment of various vital portions would be about a six hours' job; and finally I summoned to my side the head salesman on the stand and cross-examined him, with the effect that he had to plead guilty. Judge of my amusement to see this identical machine awarded nearly full marks for design in the last Quarterly Trial—I must really congratulate the A.C.U. on withdrawing those markings. In the interim since the Show I have received some dozen virulent letters complaining of the inaccessibility of parts on two or three machines there noted in my book, and therefore I recommend purchasers to be especially watchful on this point whenever they nibble at something new.

A Rained-out Magneto.

At club lectures the heckling is often of the silly order, but I have just heard of a real poser put to a lecturer upon magnetos at a club fixture the other week. The questioner asked the lecturer what was the best plan if a motor cycle was inadvertently left out in the rain till an unprotected magneto got so sodden that it would not spark. The lecturer was of opinion that ignition would be restored to order if the accessible portions were carefully dried by hand—exterior surfaces, contact breaker, carbon brush, etc. The heckler denied that this treatment had sufficed in his experience; whereupon the bold preacher, taking the bull by the horns, told him it was perfectly safe to remove the magneto and bake it for an hour or two in an oven at a gentle heat. As a matter of fact all magnetos are baked to remove damp during manufacture, and hence there is no danger in such a proceeding, provided a moderate heat is not exceeded. I can see some worried reader removing his wires and making a petrol fire under the magneto when such a mishap overtakes him!

Room for Improvement.

I live in a cascade of grumbles showered upon me by ardent and inventive riders, and I notice that two items of a motor bicycle's mechanism figure most frequently in the complaints. The first is the belt-fastener. Many riders assert that the market still lacks a thoroughly strong and satisfactory fastener, applicable to all makes of V belt. If this is so, the desiderata of a perfect fastener are that it shall be unbreakable, easy to attach, and detach; preferably it should further be adjustable.

The other item is the attachment of the exhaust valve spring cap. After fifteen years of petrol engines we still cling to the old slot and cotter, which is only easy to remove when a special tool is available, while the cotter may snap, or burr so that it cannot be withdrawn without filing, and similarly the edges of the slot may "spread" so that the cap cannot be slipped off. Is there no better way? And while I am on that point, is it not time that all valve tappets were made adjustable, and if so that the adjustment had no bad habit of re-setting itself while the engine is working?

Variable Gears.

Let me again emphasise the fact that nowadays efficient and reliable variable gears are to be had. The rider who has not owned a variably geared motor bicycle has no conception of the joys of motor cycling. To fear no hill under any conditions whatsoever is a great thing; while starting on the low gear is far and away the pleasantest method of starting I know. It is obviously better under any conditions than to sprint along wheeling two hundredweights of dead metal for it consists solely of pushing the machine along at a walking pace till it fires, lifting the valve, stepping coolly on board while there is still way on the machine and then dropping the valve once more. Though the improvement of the standard types of single speeder has certainly retarded the popularity of the variable gear, yet to my mind a good variably geared machine is almost as far ahead of the best single geared machine as the single geared machine is ahead of the 1905 3 h.p.

Many riders have not had an opportunity of seeing a good variably geared mount smartly demonstrated. I still remember the dazed astonishment writ large on the faces of certain clubmen when a visitor brought a good two-speeded mount to one of their runs. Yet all he had done was to kick it off from rest with his feet, start from rest on the bad knuckle of their test hill and climb two 25% cinder paths on a railway station embankment. It irks me to read in official reports of trials that multi-speed gears are hardly necessary, when I remember the hill-climbs in the last A.C.U. trials.

The riders were all more or less experts, the machines mostly new, and all specially tuned, not only at the outset of the run, but immediately previous to the climb. Each man had an hour before breakfast that morning, each man had an hour at the foot of Dinas Mawddwy, and a quarter of an hour, if he wanted it, at the foot of Festiniog, Wenlock Edge, and Birdlip. Yet the majority of the riders failed up Dinas, and a good percentage failed on the other hills named. Yet a multi-speed gear is hardly necessary! If variable gears ever become strictly unnecessary, a great many riders will continue to regard them as very convenient and desirable possessions.

Bradford M.C.C.

The annual open hill-climbing competition for motor cycles organised by the above club is to be held in the middle of June.

Glasgow M.C.C.

The annual general meeting will be held at the Religious Institution Rooms, 200, Buchanan Street, Glasgow, on Thursday next, the 24th inst., at 8 p.m. Several items concerning the 1910 programme will be brought up for discussion. Unattached motor cyclists are cordially invited to attend.

A Proposed Club for Leicester.

Another attempt is to be made to form a club for motor cyclists in Leicester and district, and it is hoped that this time all riders will band together to protect their own interests, and indulge in runs and competitions. Dr. C. B. Moss-Blundell sends us notice of a meeting to be held at the Stag and Pheasant, Humberstone Gate, to-day (Monday) at 8 p.m., and all interested are invited to attend.

Liverpool M.C.

The Liverpool Motor Club held its club supper and smoker at headquarters, St. George's Restaurant, Liverpool, on the 11th inst. Some thirty members sat down to an excellent repast, followed by a musical programme arranged by Mr. Woodley Jarvis. The secretary, Mr. E. L. Fehr, thanked Mr. Woodley Jarvis and the several artistes for their kindness in entertaining the members. Mr. W. Jarvis responded for the artistes.

Dublin and District M.C.C.

The fixtures for March, April, and May have been decided upon as follows: March 17th—Opening run; meet at Enniskerry at 5 p.m. for tea. March 23th—Run, Wicklow to Bray and Newtownmountkennedy; Donnybrook 10 a.m. March 28th—Run to Maryborough; Inchicore 10.30 a.m. April 16th—Paperchase Competition; meet at Donnybrook 3 p.m. May 7th—Run to Glencullen; Donnybrook 3 p.m. May 16th—180 miles open reliability trial to Lisburn and back for White Cup. May 21st—Run to Navan; Gough Monument 3 p.m.

Scarborough and District M.C.

The second annual general meeting will be held on Monday next, 28th inst., at the Pavilion Hotel, commencing at seven o'clock when the balance-sheet and annual report will be submitted and committee and officers elected. After the business part of the meeting has been transacted, Mr. R. W. Ingrose, of West Ayton (chairman), will present the prizes to the various winners in last year's competitions. At nine o'clock Mr. W. W. Hodgson, of Richmond (Yorks), hon. solicitor, will read his paper entitled "The Law Relating to Motoring." The balance-sheet shows a substantial balance in hand.

North-west London M.C.C.

The regulations for the inter-club competition with the Herts County M.C.C. to Harrogate and back at Easter have now been drafted. For this event the Service Co., of Holborn, have presented a solid silver challenge cup value £10. The outward journey will be made from Highgate on Good Friday, March 25th, the return being on Monday, March 28th. The marking will be on the basis of 100 marks for each journey, with a mark deducted for each minute early or late at the different checking stations.

On the Saturday a hill-climb will be held with the Harrogate M.C.C. Sutton Bank is proposed as the venue.

East Sussex M.C.

A meeting of enthusiastic motor cyclists was held at the Clifton Hotel, Eastbourne, recently, with the object of forming a club to be known as above. It was decided to hold a further meeting on Wednesday next, the 23rd inst., at 8.30 p.m., at the same place, to which all interested are heartily invited. Mr. R. G. Hudson is the hon. sec.

Oxford M.C.C.

The Rev. Basil H. Davies, president of the Northamptonshire Motor Cycling Club, will give an elementary talk on "Aeroplanes" before the members of the Oxford M.C.C. at the Creamery Café, 23, Cornmarket Street, Oxford, at 8 p.m. to-morrow (Tuesday). All motor cyclists and those interested in the subject will be heartily welcomed.

Newport (Mon.) and District M.C.C.

The first meeting was held at the Queen's Hotel last week, when the committee and officials were appointed. The attendance was good, and hopes of a strong club are entertained. Mr. J. Pritchard, Central Chambers, Newport, was elected hon. sec. *pro tem.*, and would be pleased to enrol any motor cyclists in the district.

Bishop Auckland, Darlington, and District M.C.

"Internal Combustion Engines as applied to Motor Cycles and Vehicles" was the title of a lecture delivered by Mr. S. F. Hill. It was the first lecture promoted by this club. The lecturer had an interesting and instructive set of lantern slides, and also actual models lent for the occasion by the Triumph, Rex, L.M.C., Douglas, Daimler, and Argyll Companies. A feature of the lecture was the detailed comparison between the working principles and efficiency of engines working on the two and four-cycle systems. The audience comprised about sixty members and their friends, and appreciation of the clear manner in which the lecturer dealt with the various technical details was frequently shown.

The chairman of the club, Mr. T. W. Craig, presided, and at the conclusion Mr. A. R. Poole proposed a vote of thanks to the lecturer, which was seconded by Mr. N. Dewhirst.

On Wednesday next, at the King's Head Hotel, at 8 p.m., Mr. J. Bellerby will lecture on "Benzol."

Belfast and District M.C.C. (Formerly Shamrock M.C.C.)

The A.G.M. of the Shamrock M.C.C. was held on the evening of the 10th inst., at the headquarters, Prince of Wales Hotel, Belfast, Mr. Beatty presiding.

The secretary's and treasurer's reports were read and passed, and satisfaction was expressed on all sides on the state of the accounts, which showed a balance in hand.

On the motion of Mr. Sharpe, seconded by Mr. Millar, that the name of the club be changed, there ensued a lengthy and interesting discussion, with the result that finally the motion was agreed to unanimously, the name of the club to be henceforth the Belfast and District Motor Cycle Club.

A good programme is being arranged for 1910, and riders of lightweights and heavyweights will be catered for.

The adjourned general meeting will be held at the headquarters on Thursday next, the 24th inst., at eight o'clock. All motor cyclists are cordially invited to attend.

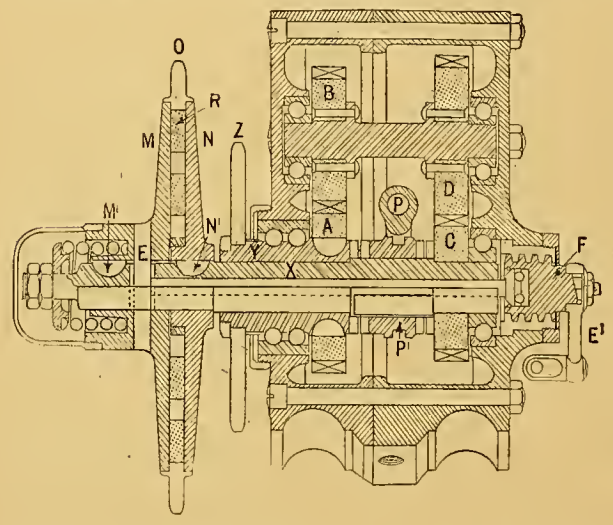
NOTICE TO CLUBS.

We would remind club committees in arranging fixture lists for 1910 that the club championship, or the M.C.C. Team Trial for *The Motor Cycle* massive silver challenge cup, is arranged to take place on Saturday, June 18th, probably in the neighbourhood of Daventry. Last year there was a record entry of eighteen clubs.

The Indian Two-speed Gear and Free Engine.

SIDECARISTS will welcome the arrival of the 7 h.p. twin-cylinder Indian with two speeds and free engine, as it is one of the few variably geared chain-driven twins on the market. The change-speed gear is a new departure in Indian practice for 1910, and is a sign of the times. 4 h.p. and 7 h.p. bicycles fitted with this gear, it is expected, will be ready for delivery in England next month. The gear, which is illustrated on this page, is of exceedingly simple design. It is on well tried lines, the principle being by no means new. The gear box is neatly fitted between the engine and rear wheel, and occupies the position of the usual bottom bracket. The clutch used in conjunction with the gear is a higher development of the compensating sprocket used on Indian motor cycles for some years.

Referring to the illustration, the four pinions A, B, C, and D are always in mesh. Gears B and D are



fixed on the counter-shaft. The engine drives by a chain from its small sprocket on to the loose sprocket O, which is clutched between the two discs M and N, cork inserts R providing the frictional surface. Both the discs M and N are keyed to the main shaft X, but while N is firmly fixed by the key N_1, M is free to slide on the key M_1.

The spring shown under the cap, on the left-hand side of the drawing, forces the disc M to the right, holding the sprocket O firmly between the two discs M and N, as already described. This forms the free engine feature of the device, and to release the clutch the lever E_1 is operated by a pedal on the left-hand side of the machine, and turns the coarse thread F, thus forcing a pin which slides in the hollow shaft X against E, so compressing the spring and freeing the sprocket O.

The central outside portion of the shaft X is squared, and upon it slides the dog clutch P_1, which has four heavy teeth on each face, corresponding with similar teeth on the pinion C and the loose sleeve Y. This clutch is operated by the shaft P, which extends through the outer case and is connected with a cross-bar, from either end of which wires extend up to the control lever on the top tube.

It is evident that if the clutch P_1 is moved to the left it locks the shaft X to the loose sleeve Y, and there will be a direct drive from the sprocket O to the sprocket Z, which latter is firmly fixed to the sleeve Y. This is the direct drive on top gear.

If, on the other hand, the clutch P_1 is moved to the right to engage with the pinion C, the drive will be from the sprocket O on to the mainshaft X, through the clutch P_1 and pinions C and D, to the counter-shaft, thence by means of the pinions B and A, which latter are firmly keyed to Y, to the sprocket Z. From Z the drive is by chain to the rear hub. The neutral position is formed by placing the clutch R midway between the pinion C and the sleeve Y.

The reduction in gearing from high to low is about one-third.

All gears and shafts are of substantial construction, with large bearing surfaces, and as the gears are always in mesh, there is no possibility of stripping them, while the teeth of the dog clutch are so cut as to facilitate engaging or disengaging when the plate clutch is released.

All shafts are carried on ball bearings, while a ball thrust washer is provided at the right end of the clutch operating pin to take up the thrust of the spring when the clutch is released. When the clutch is engaged there is no end thrust.

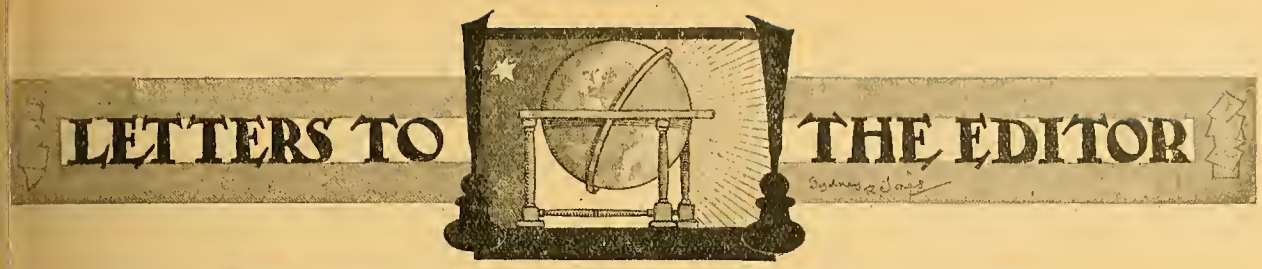
The gears are lubricated by splash, while the clutch is of the dry plate type, which is gaining such favour with car engineers.

The question of accessibility has not been lost sight of in the method of mounting the gear box, which is so cradled as to be readily and easily removed should occasion require.

A.C.U. QUARTERLY TRIALS RESULTS.

LAST week we pointed out that only one mark now separates the first eight trials competitors in the running for the silver cup. We have since received an amended list of marks awarded by the judges, but it is unnecessary for us to reprint this, as the chief alterations are the amended totals consequent upon the marks originally awarded for general excellence of design having been cancelled. The only other alterations are: F. Thomas (6-7 h.p. G.O.K.), non-stop, one hundred marks for reliability; W. G. Ayling (3½ h.p. Midget Bicar), two stops (sooted plug and ran out of petrol), eighty marks for reliability; J. Marshall (3½ h.p. Triumph), one stop (tyre trouble), ninety marks for reliability; N. C. Dear (1½ h.p. Wanderer), failed Rectory, outside time at Banbury, eighty-five marks for reliability.

In the Chancery Division of the High Court on the 4th inst. Mr. J. A. Taylor, 237, Hertford Road, Edmonton, N., who is the owner of a registered design of a dust and wind screen for application to tricars, sidecars, and trailers, secured a perpetual injunction against the Flag Patents, Unlimited, Tooting, restraining them from infringing such registered design.



The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, E.C., and should be accompanied by the writer's full name and address.

Belts on Lightweights.

[4579.]—In reply to your correspondent E. McQuade [letter 4536] regarding belt slipping. The belt has slipped slightly in heavy downpours, but I have never been stopped by same. On hills I generally assist with the pedals without, however, straining myself in the least. The above applies to very wet weather. HARRY SHARPE.

A Novel Belt Tip.

[4580.]—During the belt controversy which was recently raged in your columns, I noticed several contributors were lamenting at the number of fastenings they used. It might interest them to know that during the last two years I have fought but three, those being the Stanley with adjustable hooks. For the screw I substitute a French or clout nail and copper washer. The washer is knocked down the nail with pliers very tightly (so compressing the belt in fastener), oil is then cut to size and burred—a punch is unnecessary as a sharp awl being quite sufficient. A file soon removes rubber when shortening is required. I might mention the hook end anchorage of a leather belt I used last year was not interfered with for the 1,500 miles I covered with it. Hoping this information will be of service to others,

G. WILSON.

General Recognition of Motor Cycle Records.

[4581.]—I regret to say that in the past a certain amount of discredit has been unjustly thrown upon American records, and I have been particularly careful in getting up the latest lists of records [See *The Motor Cycle* of January 31st.—ED.] to eliminate, as far as possible, any chance of error. It seems to me that it would be a desirable step for the Auto Cycle Union of Great Britain and the F.A.M. to get together once a year and publish under their authority a set of world's records for the past year. I am willing that the Auto Cycle Union should appoint a committee of reliable men in this country to go over the records, and the circumstances, places, and times in which they were made, and pass them. If they can convince me of any error, and I assure you that I am open to conviction, no one will be quicker than I to ratify it. J. P. THORNLEY,

Chairman Federation of American Motor Cyclists.

Water-cooling on Motor Bicycle Engines.

[4582.]—I have read all the correspondence that has appeared in *The Motor Cycle* regarding water-cooling on motor bicycle engines, and I am of the opinion that a water-cooled head, if it can be arranged without unduly affecting the weight or reliability, would be a great advantage, but I cannot help but think of the days when I owned a water-cooled De Dion tricycle, which was stored in a shed at some distance from my house. Whenever the temperature fell below a certain point in the winter time, I was always nervous about the freezing of the water in the radiator and head, and, despite the many advantages of water-cooling, it was a nuisance to have to run the water out. In the case of readers who have facilities for storing in outhouses or stabling where the temperature is always kept above freezing-point, it is immaterial whether air or water-cooling is employed, but I think it will be agreed that the majority of motor cyclists have not these advantages. True, a motor bicycle can be brought into a dwelling house if occasion requires, but it is an awkward thing to store in a house whose rooms are of small dimensions.

CULASSE.

A Valve Grinding Tip.

[4583.]—I thought the following tip might be of use to readers of *The Motor Cycle* regarding grinding of valves and cocks. I have been called in to explosion engines, oil, gas, and petrol, and upon examination have, with a few exceptions, found the valves are well ground in, but have no face or polish. The majority of riders seem to think that a rub with emery makes matters all right, and so it does to a certain extent, but the valve seat, which is usually cast iron, is, upon examination, scored, and distinct rings can be traced where the emery has cut deeper in one place than another. After fine flour emery and oil have been used, especially on petrol taps, the emery bites into the cock, and it is extremely hard to turn. Special attention should be paid to finishing or polishing up the seating or body of petrol and compression cocks. After a good facing with flour emery rinse off all emery with petrol and dry with cotton rag, and apply a little Globe metal polish, and finish. If properly done the grinding of a valve or cock can be highly finished in this manner, as the fine particles of the polish make a very fine grinding medium. E. ARMSTRONG.

Road Dangers at Night.

[4584.]—I have read a lot of complaints in *The Motor Cycle* regarding road dangers at night. I would like to inform some of the English motor cycle riders that they do not know what road dangers are. In this country motorists have always to keep a constant look-out for road dangers, even in the daytime.

While riding the other week I came across a flock of goats in the road; and another time, while riding from Johannesburg to Pretoria, I ran into a herd of bullocks. On both occasions there was no one in charge of the herds.

Big stones in the middle of the road are another road danger in this country. These stones are a nuisance to cyclists and motor cyclists. While riding at nights one has to be always looking about for fear of running off the road, and I have often done this. One night I ran off the road and was almost killed, for I dropped into a pit. No doubt some of your readers will wonder how I came to run off the road. Unlike England, the roads here are just made across the veldt. There are no hedges and no railings, and it is a case of finding your own road.

Now I think that if some of the gentlemen who complain of the road dangers at home could come out here, and do a bit of motor cycling, they would not be so eager to complain of the English road dangers. G. EVER.

Transvaal.

A Puzzling Case.

[4585.]—Mr. F. Lucas, who contributed the article under the above heading on January 10th, invites opinions of the cause of the singular behaviour of his Triumph machine. I do not think that the sparking plugs are entirely to blame, and am convinced that if Mr. Lucas enlarges the jet orifice to its original size his trouble will cease.

The cause of the trouble appears to be due to the adjustment of the carburetter. The mixture is evidently of satisfactory proportions when the throttle is nearly closed—when only a small quantity of air is admitted—but when the throttle is open wide a large amount of air is drawn in, but the burred up jet orifice cannot pass the requisite amount of petrol. A mixture is thus produced which burns so slowly that the power rapidly falls away and back fires and ignited petrol in carburetter the result.

This trouble is temporarily lessened by the substitution of a cleaner sparking plug as a hot spark is thus produced, and

the weak mixture fires and burns quicker, so that the troublesome symptoms are therefore not so quickly apparent. I have often experienced the same trouble with my twin, but generally there was a total cessation of firing when the throttle was opened. In my case an immediate cure was the cleaning of the carburetter jet tube.

J. F. ADYE.

American Records.

[4586.]—Replying to letter 4493, January 10th, signed "Colonial," regarding American records, I fail to see the connection between Dr. Cook and the motor cycle. However, the only country to recognise Dr. Cook's claim to Polar discovery was a European one. America waited for verification. Perhaps "Colonial" has heard of a certain Lieut. Peary, another American, who did reach the Pole, also of numerous Britishers who did not.

It seems to me that the Indian has demonstrated in England the possible accuracy of published American records; besides, it is hardly likely that audiences of several thousands would repeatedly submit to being fooled by faked records. Americans showed, some hundred odd years ago, that at that early date they were not altogether fools.

Will "we Britishers" send some of your fast machines to America and compete against the American machines, as the Hendee people have done in England? We Canadians hope so. Englishmen are usually considered good sportsmen, but it is not too sportsmanlike to be continually doubting records because you cannot make as good.

I shall look for the smiling Indian in Wells's space in *The Motor Cycle* after the first meeting between the "big 7 h.p." and some of the English machines.

Toronto, Canada. ANOTHER COLONIAL.

Lightweights v. Heavyweights.

[4587.]—Like your correspondent the Rev. R. Measures, I, too, am a clergyman and the possessor of a heavyweight. I live in a large town, and though I am young and of more than average strength, yet I find my machine far too fatiguing for daily riding in traffic, dodging about from house to house and from village to village.

Mr. Measures, no doubt, has a cure somewhere in the country where no traffic to speak of is ever encountered in his parish. Under such circumstances the heavyweight with free engine may prove suitable enough, but I wonder whether he has any experience of what it means to pay a round of calls in all weathers on a heavy machine in a very busy town day after day for, say, a year. I am afraid he has had no such experience, for he lives entirely in the country, and to this discussion he brings an experience of the country and of the country only. As a test of the superiority of the lightweight in traffic, let him journey from, say, New Cross through the heart of London to Crouch End, first on a lightweight and then on a heavy. Whatever the advantages the latter may have as a touring mount, he will certainly come to the conclusion that for dodging in and out, stopping and starting, pedalling without fatigue behind crawling vehicles, handiness and convenience, the lightweight is an easy winner.

For traffic and frequent calls one does not need a fast and powerful machine, but one which will travel at a moderate pace, and which can be pedalled along when necessary without undue fatigue. The lightweight adequately fills that want, and the fact that by far the majority of those who now ride in and out of the city every day in all weathers use lightweights is evidence, if evidence were needed, of the increasing popularity of this class of machine.

There is one assertion in your correspondent's letter which completely fascinated me. He tells us that he starts and stops as many as twenty or thirty times in a couple of miles. That works out at one stop every 117 yards! Under those conditions I would not even use a push bicycle. Mr. Measures cannot be serious. What on earth does he stop so often for? I see from the directory that he lives in a little hamlet in Sussex where for miles around one scarcely comes across one house in two miles, let alone twenty or thirty. If Mr. Measures stops so often in two miles it must be for divers other reasons. RUS IN URBE.

[4588.]—In the controversy on the above subject, I think one aspect of the matter has not been mentioned by anyone. Granted, as it must be, that the great majority of riders keep and use their machines for pleasure and long-distance riding, what does it matter, once the machine is got going, what its weight is? I have ridden (not owned) a lightweight, and, frankly, did not like the experience. I owned and used during 1908 and part of 1909 a 3½ h.p. Triumph, and, good and reliable as it is, here in hilly Devon, unless in perfect tune and new, it also has its limitations. Oh! I know the reply from Triumph enthusiasts—"Keep it in perfect tune then." But steady, my friends. I was returning last Easter Monday from a lengthy tour to Plymouth. The first part of the holiday had been blazing sunshine and dust (oh, that dust! and my poor carburetter, just fixed in the very place to take in a maximum); the last day, Easter Monday, it rained, and that finished us both. How about tuning then, my friends? It jibbed on the long hills, and I did not enjoy the last day of my holiday.

I decided then that what was wanted was more power and a two-speed gear, and I got both when I purchased an 8 h.p. Bat, P. and M. two-speed gear, and J.A.P. carburetter, and now I know what real luxury is. No longer have the most terrifying hills any terrors for me; the machine "eats them up," as the advertisement says; slow as one can wish in traffic, anything up to between 60 and 70 m.p.h.—and an enormous reserve of power. Out of tune does not trouble me any longer; I can easily tune up at home and at my leisure.

How Mr. W. H. M. Pattisson carries his dog about on his motor bicycle. The terrier sits in a light openwork basket which is suspended from a leather strap round the rider's shoulders. Mr. Pattisson says: "The dog seems to enjoy riding my Triumph as much as I do, which is saying a good deal."

Weight! What does that matter; we are out to ride, not push, and I have never had to do so yet. Half a dozen steps with the low gear in and it starts. I can start up on the steepest hill, and, by the way, if the End-to-end ride were taken from Launceston to Exeter, *viâ* Tavistock, Princetown, and Moreton Hampstead, I belive we should see something. Just take a look at the Contour Book, Mr. Editor. Anyway, the machines would have, on the first day out, as severe a testing as the most enthusiastic could wish for. I did the journey on the 3½ h.p. Triumph, and I have done it on the 8 h.p. Bat, and know the difference. I am not particularly young (shall not see thirty again), and neither am I remarkably muscular (rather the opposite); and as to my nerves, I know I have them, and doctors say that if they are in perfect condition we do not know we have such things; inference, mine are not perfect.

I have no interest whatever in the Bat Co., having purchased the machine after noticing its consistent behaviour in last year's trials, especially on the hills (my bugbear).

JAS. EDGCOMBE.

The A.C.U. Quarterly Trials.

[4589.]—I should like to inform your correspondent, Mr. Eli Clark, that I am fully aware that I had two stops in the recent Quarterly Trials, and also that I entered same on the A.C.U. card HAROLD H. BOWEN.

[4590.]—The official results of the last Quarterly Trials, as published in your issue of February 7th, abound in curious anomalies and inconsistencies, of which I should like to point out a few.

I believe it was decided, in consequence of the bad state of the road surface on Dashwood Hill, that no marks should be deducted for failure to climb it, and for the most part this idea was apparently carried out. Why, therefore, were there any exceptions made? For instance, W. Pratt (Phelon and Moore) fell off his machine on the hill, yet is awarded full (10) marks; D. R. Clarke (James) made a clean ascent, yet is only awarded 7 marks.

Again, Pratt, having failed on Dashwood, and forced to drop into his low gear to climb Rectory Hill, is accorded full marks for reliability, and credited with a "non-stop"; but F. W. Applebee, who came right through without a fault until he got within "sight of the Chequers Hotel," when his engine stopped for a moment (apparently without cause, for it started up again instantly without adjustment), is docked 10 marks under the heading of reliability.

The markings for "reliability" are most unsati factory when carefully looked into. Here is one instance: W. Cooper (Bradbury) fell on Dashwood and failed on Rectory, and loses 10 marks for "reliability," *i.e.*, 5 for each failure; Leno (P.M.C. two-stroke) side-slipped once and also failed on Rectory, yet he loses only 5 marks; Deacock (Wanderer) failed only on Dashwood through side-slip, yet is docked 5 marks on reliability. Why, I wonder, when Pratt gets full marks?

Newey (Norton) partly failed on Rectory through a slipping belt, but nevertheless was awarded 4 marks for the hill-climb. Underhill (L.M.C.) fails on Rectory, and gets no hill-climbing marks at all there. Presumably, therefore, his performance on the hill was slightly worse than Newey's; yet Underhill loses only 5 marks on reliability, while Newey loses 10. Barker (Clyde) has two stops (one engine stop and failure on Rectory), and loses 10 marks. Slaughter (Ariel) has two stops, yet loses only 5 marks. [Our correspondent here calls attention to marks awarded under the heading "General Excellence of Design," but as the committee has now decided not to award marks under this heading we have omitted this portion of his letter.—ED.]

Doubtless many difficulties crop up for the officials in these trials, but surely they are not insurmountable. Certainly, if the trials are to be worth anything at all either to the trade or the public, they will have to be surmounted, and the sooner the better.

May I suggest that the judges reconsider their figures, and present an amended report?

T. CHAS. PERRYMAN.

[4591.]—It is gratifying to note the increasing popularity of the Quarterly Trials, but a glance over the official table of results of the January Trials prompts me to ask if they are not losing their value.

One cannot compare the mark awards without realising they bear no definite relation to merit of performance. The lapses in this direction are too numerous to permit of individual mention, but when we notice under "Reliability" five marks only being deleted for two stops, and other machines penalised twenty marks for the same number of stops, and ten for but a single stop, what can one think? Also, how can one reconcile the published photograph of a fallen machine and rider with the judges' award to that rider of 100 marks for non-stop, and full marks for hill-climbing? If Dashwood were ruled out on account of bad surface, why are full marks awarded in some cases and other riders penalised? Surely all marks should have been deleted, or all riders given full marks.

Under "Ease of Starting" the table makes it appear that machines not fitted with a free engine are penalised. If this is so it is distinctly unfair, no competitor to my knowledge having had advice of this intention. It would be interesting to learn on what basis or standard the marks for cleanliness are awarded. The amount of road dirt on machine or rider cannot with justice be made to form this basis. If a rider is forced on to a particularly bad piece of road, or if he holds anything but the first place in a company of riders, he suffers. Imagine the official car passing a competitor bespattering him with mud, and then the officials penalising him. In the January Trials one competitor with ordinary motor cycle mudguards was heavily penalised, but the penalty was almost solely due to the fact of extra large tyres with effective rubber studs being fitted for comfort and safety. They were mud slingers, and he suffered. Another competitor had the forethought to fit small tyres for the job, and consequently stood high in the cleanliness list. The moral is obvious. Difficulties face the judges in this direction. I would suggest that under "cleanliness," oiltight or leaky engines, etc., only be considered, and that "mudguards" make another heading.

In my opinion it is incumbent upon the judges to give their reasons for deletion of marks in each instance, and an explanation of the apparent discrepancies in the rewards for reliability. If this cannot be done the trials (except from a sporting sense) have no value, and manufacturers cannot be recommended to spend money on them.

JAS. L. NORTON.

The Motor Cycle in the United States.

[4592.]—On reading letter No. 4561, signed "Disgusted Belt User," I find our friend discreetly omits to state the size of belts used on his 5 h.p. belt-devouring device. If he used a ⅝in. rubber and canvas belt as used on model engines and a leather belt as used on sewing machines, then I must say that he was courting trouble, whether those belts were made in England or America; but as I infer that he used a ⅞in. rubber and canvas or leather belt, then I must say that he is the unfortunate possessor of a very inflexible engine, if that engine, as he states, chews up belts (any kind—rubber, canvas, or leather—especially English) every thirty miles.

He states that the makers of English belts say that the climate of America is unsuited for English belts. Then what will the humid and torrid climate of Africa, India, Australia, New Zealand, and Canada do to an English belt? No, no, my friend, your yarn will not wash, because I have a ⅞in. Stanley Dermatine belt which has run two years, and is at the present time in the hands of its manufacturers for some little attention so as to allow it to run another year. But, then, my machine is a 3½ h.p. English machine, with transmission by an English belt, ridden by an Englishman in an English climate. Perhaps the affinity of the English prolongs the life of the belt.

My belt has run (not been wrapped up in a special wrapper) in hail, snow, rain, sunshine, and over roads such as Waddington Fells in Lancashire and Yorkshire, where no road roller can get, and over Shap, which would play havoc with chain transmission. The alignment of pulleys on my machine is perfect, the engine is flexible, and it is driven by the owner, who is not a millionaire, and who places implicit confidence in English productions.

I have not had the pleasure of using an American belt or an American motor bicycle, chain-driven or otherwise, but the letter in *The Motor Cycle* gives one the impression that the machine described by "Disgusted Belt User" would not have much chance in a 1,000 miles reliability trial, if it were belt-driven, unless one carried three spare belts and fasteners. MILTON RAWSTHOONE.

EXPERIENCES WANTED.

"C. O. M." (Co. Tipperary) would be glad of an owner's opinion of the A.C. tricar, particularly with regard to ease of steering and stability.

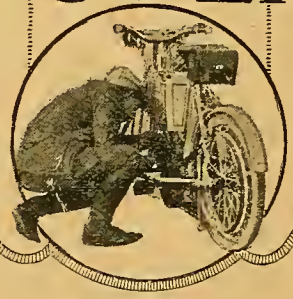
"R. B. G." (Belfast) is anxious for readers' experiences of the Douglas and Motosacoche lightweights.

"H. E. S." (Leicester) desires readers' experiences of the four-cylinder Wilkinson T.A.C.

NOTICE.

The Editor disclaims all legal responsibility in any way for loss of copy in the form of manuscript, drawings, or photographs submitted to him. Rejected manuscript, drawings, and photographs will only be returned provided a stamped addressed envelope is enclosed for the purpose.

How to Overhaul a Motor Cycle



By CON-ROD.

(*Continued from page* 117.)

Carburetter.

Grind the needle in with fine crocus powder, and, having previously ascertained that the petrol level is correct, make sure that the collar actuating the balance weights is fast. If the little pivots for the balance weights, or the holes in the latter, are badly worn, they should be replaced. Wear begets wear in increasing proportion, and if it is the rider's fate to do much travelling over rough roads, it is very probable that one day he will find himself with a balance weight, and consequently carburetter, *hors de combat*.

Of course, if it did happen it would not take a very long time to repair, even on the road, with the aid of a thick pin, wire, or, even as befell the writer, a borrowed hairpin supplied by a fair spectator; but the whole object of this article is to place the motor cyclist beyond the need of such assistance. Examine the wires of handle-bar controlled carburetters, and if either is loose or broken, resolder it, keeping a slight twist on the wire while doing so. In the case of tank lever controls, very little can be done beyond using leather washers to stop air leakage, at the points where the spindle, etc., enter the carburetter, backed up, if necessary, by a spring washer to prevent rattling.

Contact Breaker.

It is not my intention to touch upon the overhauling of coils or accumulators, as these are better left in the hands of their makers. It would, however, be as well to mention in passing that a great advantage is derived from fitting a separate condenser between the platinum points of contact breaker of both plain and trembler coil systems, and also by fitting an earth wire in the case of the wipe contact breaker from the revolving disc itself to some convenient nut on the frame or engine, and in the case of the make and break type from the platinum contact which is not already wired up. The wipe contact breaker may be easily dealt with as shown in fig. 4.

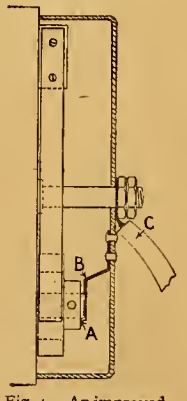


Fig. 4.—An improved "earth" or frame connection for the contact breaker.

A. Shaft carrying contact breaker.
B. Strip of brass making contact between shaft A and case.
C. Earth wire from case to frame.

The reason for adopting these precautions is that the thick dirty oil from the crank case, in lubricating the rotating parts, so coats the spindle carrying the disc as partially to insulate it when oil is cold and thick. Hence trouble when starting up and good running when hot; also refusal to fire with anything less than the full voltage. The make and break type is affected in the same way by oil getting between the contact breaker case and the part upon which it moves.

The Magneto.

In dealing with the magneto machine, a precaution which renders damage less likely, if the spindle is to be rotated, is to wire up the high-tension terminal to the magnets, and so save any strain on the armature coils. There is no reason why the spark should be forced across the safety gap merely because it exists, and many prefer not to run any risks when so simple a remedy is at hand. The majority of magneto manufacturers do not appear to have provided us with any test to indicate whether the magnets have sufficient strength for perfect results or whether they require remagnetising. The following method is therefore offered in default of a better. Connect the special Bosch magneto spanner or an ordinary sparking plug to the high-tension terminal and short the spanner (which in the case of the Bosch is just the correct length) or the body of the plug to the magneto. The points of the sparking plug must have the right gap, *i.e.*, to Bosch or other gauge. Now if a duster is wrapped round the driving wheel of the magneto it will enable a good grip to be obtained, and if the armature is now turned by hand at the same rate as one would ordinarily turn a door handle there should be a spark between the spanner and the magnets or at the points if everything is in order. For those who prefer a figure, a fair spark should occur at about 125 r.p.m. If it occurs at a less speed, so much the better. On the other hand, it does not necessarily follow that it will give a spark at this speed when the plug is in the cylinder and the space between the points of the plug is filled with gas under pressure, which causes a considerably greater resistance to the passage of the current. The platinum points should be tapped with extremely light hammer blows and filed with a special dead smooth file sold for the purpose till they meet fairly and squarely. The amount of break recommended by the makers is usually about half a millimetre (say $\frac{1}{50}$in.) Gauges are supplied by the Bosch, Simms, and other magneto manufacturers. A slight flat worn on the rubbing end of the steel rocking arm of the old pattern Bosch magneto does not have any harmful effect, but if it is badly worn, new parts are not costly; the same remark applies to the fibre ring. It is by no means uncommon to find the fibre ring worn at the point which breaks the contact in such a way as to make the break more gradual than might be desired. This may be remedied by freshening the face of the "hump" with a half-round file, smoothing it over afterwards.

How to Overhaul a Motor Cycle.—

Test both ends of the spindle for play in the bearings. If badly worn the magneto machine should be sent to its makers, as if the wear is not corrected it might cause the armature to touch the pole pieces.

Clean all carbon brushes, and see that they slide freely in their holders, not forgetting the small brush in the contact breaker plate, which bears on the brass body behind and provides an earth return. The oil wells should be washed out with paraffin, the screws at the bottom being removed to drain away the dirty oil. All superfluous paraffin should be mopped out with spills of blotting paper, and the parts replaced and stored in a warm dry place till wanted, when the oil wells should be replenished with magneto oil. Whilst on the subject of magnetos, it may perhaps be as well to mention that there are devices sold for protecting the terminals from mud and wet, but if one or other of these is not available get a short piece of rubber tube about 1½in. long and a tight fit over the insulator carrying carbon pencil and terminal. Make a small hole in the side of this just big enough to squeeze the H.T. wire through, and in such a position that, when the wire is connected up, it will help to keep one end of the tube hard up against the magneto casing. Cut the other end so as to clear the terminal by an ⅛in., and fit into it a disc of rubber, which can be cut out of an old inner tube. Clean the edges and outside of this, and solution it to an ordinary patch large enough to cover the tube. When dry carefully seal the open end of the tube with this cover, again using solution (see fig. 5). This will be found equally effective for horizontal and vertical positions, provided always that the tube is a tight fit over the insulator and the H.T. wire a tight fit in the side of the tube.

Single Cylinder. Twin Cylinder.

Fig. 5.—High Tension Terminal Protector

A. Wire to sparking plug.
B. Insulated terminal.
C. Rubber protector.
D. Cap for ditto.

With regard to magneto drives, there is not much to be said. The transmission very rarely requires attention if it has been well lubricated. See that the slots in the magneto platform fitted to the machine provide plenty of movement for adjustment and sufficient for correct alignment.

Attention to the Engine.

Clean the whole of the engine externally before taking the cylinder or cylinders off, otherwise dirt is sure to get in the crank case, which may not need dismantling. Having removed the cylinder, chip and scrape off the carbon deposit from the head with a long cold chisel or screwdriver, taking care not to damage the fins. Unscrew all removable parts from the cylinder head such as compression taps, plugs, and valve caps or a.o.i.v. seat. Scrape all these clean, so as to show the colour of the metal. Try the cylinder for wear in an oval direction with inside callipers or a micrometer. If this is as much as four of five-thousandths of an inch the cylinder should be sent to be ground out on a grinding machine; otherwise it may be allowed to pass for the present. Any serious scores on cylinder walls would also render grinding out advisable. Now measure the largest diameter of the cylinder very carefully at a point about ½in. below the top of the travel of the piston. Compare this by the aid of outside callipers and feeler gauges with the diameter of the piston across the divisions between the rings. If there is a difference of as much as twenty-five-thousandths scrap the old piston and order a new one, as the best fitting rings would give only very indifferent service under such circumstances, and would be nearly sure to break at an early date. If it is decided to have the cylinder ground out, another two-thousandths should be added to the actual measurement of the piston at its largest diameter when ordering. In cases where motor cyclists do not feel capable of making these measurements themselves they must submit cylinder and piston to the makers or one of the firms who make a speciality of grinding and fitting new pistons. Many people make a mistake in thinking that they have made a good job of fitting new piston rings when they are only just able to make them enter the mouth of the cylinder. The mouth of a cylinder receives less wear than any other part, and a ring which will barely pass it may have a gap of something like an eighth of an inch when it expands higher up in its working position. At the same time, obviously it is no use making the ring any larger in diameter, because it would not enter the cylinder at all. If this is the only trouble with the cylinder, it may be lapped out by hand with the aid of a wooden dummy covered with emery cloth. The dummy should be a fair fit in the mouth of the cylinder, and may have powdered emery and oil sprinkled on it from time to time. As the grinding goes on, the dummy may be enlarged by placing a layer of brown paper under the emery cloth. Those who have ever done any lapping out will know that much patience is also required. Should the original piston be retained, see that the sides of the ring grooves are parallel. If this is not the case the new rings will bind in the grooves, and, even if they do not break, will cause excessive friction and wear on the cylinder walls.

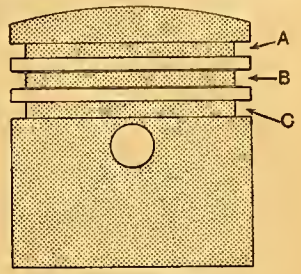

Fig. 6.—Wear on Piston.
A. Ring groove when new.
B. Badly worn groove.
C. Groove turned out to suit new and deeper ring.

A great deal is to be said in favour of step-cut rings, and wherever possible new pistons should be provided with this form. But here again a lurking danger besets the unwary who might be tempted to fit step-cut rings in an ordinary piston. They are usually about double the width of ordinary diagonally-cut rings, otherwise the steps or projections would have to be very thin and would probably break off. This means that the best you could do with a piston arranged for three diagonally-cut rings would be to turn off one of the divisions in the piston and fit a new broad step-cut ring in the broad groove thus provided, retaining one ordinary ring. I do not recommend this, as the effect, owing to the greater inertia and strength of the big ring, would probably be to shear off the remaining division or divisions, and the next time the cylinder is removed you would find all the rings stuck at the top of the cylinder. This has happened within the writer's knowledge. The divisions between the grooves should not be less than the width of the rings they retain, measured in the direction of travel.

How to Overhaul a Motor Cycle.—

Clean the Piston Inside and Out.

Make a point of cleaning not only the top of the piston, but also the inside. The accumulation of dirt here adds to the weight of reciprocating parts, and will cause the engine to be badly balanced. Withdraw the set-screws—if any—and examine the gudgeon pin for play in the lugs of the piston. If there is any undue wear, scrap the pin and have a larger one turned, as it is a hopeless thing to make a good job of it by bolstering up with the set-pins; in addition, they are sure to break away the boss if much pressure be placed on them. For a really sound job, a plain gudgeon-pin with a very slow taper—about $\frac{1}{32}$in. to the foot—cannot be beaten if it is made to bear all the way through the piston and is driven home tight. It should be made at least double the length actually required, so as to allow for fitting and grinding-in. The last time of fitting, it should be driven up tightly but firmly until there is practically no more movement, and then the big end of the pin should be cut off $\frac{1}{8}$in. from the piston. The pin should then be driven out and the small end cut off, making the total length of the pin $\frac{1}{8}$in. less than the diameter of the piston. Put a saw cut in the big end of the pin so as to know which way to knock it out. In driving it in care should be taken not to force it too far, or the piston may be distorted. Light blows are sufficient, as the wedging action of the taper will cause it to remain in position.

If the little end of the connecting rod has too much vertical play (rocking and side play do not matter in either end; in fact, to a certain extent they are necessary), it should be rebored or lapped out to suit the new pin; or, if retaining the old pin, fit a new bush. Play in the big end must be treated in the same way, except in those cases where the crank-pin requires replacement, when this should be made a little bigger and the old bush lapped out. Outside flywheel engines and others not having built-up cranks and flywheels are more easily dealt with by filing down the faces of the split brasses. Scrape out the oil holes and grooves in all bearings and moving parts, and smooth over any scratches or scores not sufficient to warrant new parts.

Main Shaft Bearings.

If plain bearings are used for the crankshaft it is a fairly simple matter to estimate the amount of wear left in them; and, even if they should be a bit slack, they may be relied upon for wearing gradually and not letting you down all at once. Make sure that the bush itself is a tight fit in the crank case. Ball bearings for the crankshaft must be treated with more care, and when once wear has taken place to any extent, they are less able to resist the hammering effect resulting from it than a plain bearing. Those accustome to plain bearing engines should remember this when dealing with the newer type. Bushes throughout the timing gear need attention, especially those supporting the exhaust valve cam wheels. The drain hole in the crank case should be about $\frac{3}{16}$in. in diameter, if it is to be of any real use in getting rid of dirt as well as oil. If the draining is effected quickly, after pedalling the engine round with paraffin in the crank case, the dirt will not have time to settle, and will be carried out in suspension. The engine pulley groove is almost sure to be worn, and should be trued up to 28° in a lathe.

Valves.

The exhaust valve usually gets a lot of grinding, and it is curious that more riders do not adopt some such simple plan as shown in fig. 7, for a two-fold reason—firstly, it greatly facilitates the process, and secondly, it saves the greater part of the wear on the valve seat, the effect of which is shown in fig. 8. Fig. 7 is merely a dummy valve seat made of hard cast-iron.

The wood pattern is exactly similar to the casting required, and, being very simple, could be made by anyone possessing mechanical ability. The pattern is best made solid, the holes being bored out afterwards. The seat may be trued up from time to time in a lathe, if required, by running a good-fitting mandrel through the valve-stem holes, placing this between the centres and putting the carrier on the end guide itself.

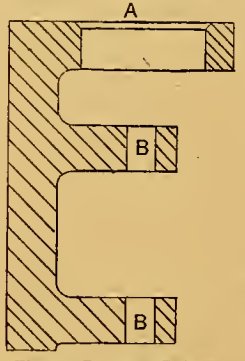

Fig. 7.—Dummy Exhaust Valve Seating.
A. The seating.
B.B. Holes for exhaust valve stem.

The dummy should be made roughly of the proportions shown in the sketch, so as not only to stand a fair amount of knocking about and reseating once or twice, but also to prevent springing when being turned in the lathe. Everyone has probably noticed that a perfect seat is obtained in the cylinder with very little grinding. All the subsequent work required to produce a good seat on the valve is wearing away and weakening the seat in the cylinder. The old valve should be ground in to the dummy first till the valve is bright all round, then grind the valve in the cylinder seat till this is also bright all round. The difference will be that very much less grinding will be necessary on the cylinder seat itself owing to the valve seat having been already ground on the dummy.

In the case of an engine used by a hard rider, and which had been in commission for three years, the cylinder seat was found to be nearly $\frac{1}{8}$in. below its proper level; hence an otherwise unaccountable loss of power. It gave just such symptoms as one frequently sees described in this paper, *i.e.*, carburetter, ignition, compression, timing, etc., all perfect. Machine will not run fast, will not climb, and overheats. Now when you consider that this valve had only about half its full effective lift, and that it was virtually opening late and closing early at the valve head—although judging by the stem it might be supposed to be absolutely correctly timed—you will easily see ample reason for bad running. Fig. 8 shows clearly the throttling effect, as the valve head was found to be very little smaller than the recess it had worn away, thus preventing any appreciable valve opening till the head had moved out of the pocket.

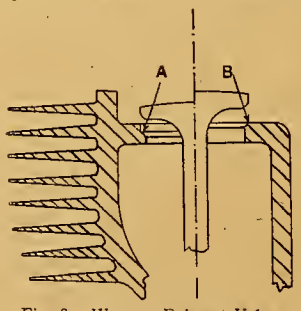

Fig. 8.—Wear on Exhaust Valve Seating through Constant Grinding.
A. Worn seat showing reduced effective valve opening.
B. Valve seat when new showing full valve opening.

How to Overhaul a Motor Cycle. —

The remedy for this evil is to bore away the valve chamber face till it assumes the shape shown by dotted lines in fig. 7; in other words, to carry on the line of the existing valve seat till it meets the valve chamber floor. The inlet valve and seat are not subject to the same wear, and rarely require any such attention, though the automatic valves in some engines are prone to enlarge the guide and get "crossed" on the seat, resulting in a blow-back through the carburetter. These valves should always be kept as light as possible, thereby saving some of the lag when opening and also enabling them to close quicker.

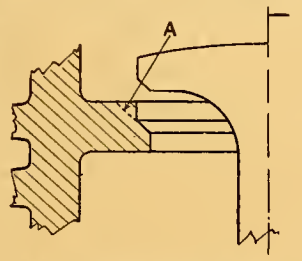

Fig. 9.—Enlarged Section of Exhaust Valve Seating.
A. Dotted line indicates the manner in which the worn seating should be turned out to increase valve opening.

Holes in Inlet Valve Seatings.

Makers are sometimes rather scanty with the holes in the automatic inlet valve seat. Enlarge these if possible, as the gas is warmed by the time it gets to them, and consequently they have to deal with a bigger volume than the inlet pipe, where it is colder.

One hears complaints about the clicking of tappets now and again, but in many cases this sound is not due to the impact of the tappet on the valve stem or in the rocker, but to play in the 2 to 1 gear, and it occurs as follows: At the end of the power stroke the exhaust valve begins to rise, taking all the back-lash out of the gear for the time being, and the two remain in steady engagement during the whole of the exhaust stroke till the cam has passed the period of rest. Then the thrust of the strong spring suddenly acts on the reverse side of the cam, with the result that it now pushes the cam in the opposite direction, and it goes over with a click and slight concussion, caused by the teeth of the gear being now engaged on the other side, proportionate to the amount of play in the gears and the strength of the spring.

Locating Noise in Timing Gears.

Fibre washers on the tappet end may partially deaden sound produced by blows struck on the stem of the valve, but they will not cause the cam gear to be one iota more silent when the noise is caused by play in the 2 to 1 gear. It is very easy to test whether the sound comes from this source or not. Wheel the machine along very slowly with the compression tap open and not using the valve-lifter. Watch the tappet very carefully, and note if, after reaching the maximum lift, it suddenly slips down a little bit before it commences the descent proper, when the click will be heard. This will prove without a doubt that the sound is due to worn or badly-cut gears. Owing to its origin, the noise is going on at all speeds until the spring fails to close the valve correctly.

Sparking Plugs.

If all old sparking plugs are kept, spares may often be fitted up by using, say, the porcelain of one with the body of another and the electrode of a third, but they should all be tested by actual use before relying upon them. The packing rings of the plugs should be attended to, as a leakage at that point renders the plug parts almost incandescent, and will make the engine back-fire and come to a sudden stop, after running some time satisfactorily, or if the throttle is opened widely. The symptoms of this are identical with those described under the heading "A Puzzling Case" in a recent issue of *The Motor Cycle*.

Importance of Compression-tight joints.

In conclusion, it is assumed that the reader will take all ordinary precautions to secure gastight joints in the cylinder head and valve seats, and oiltight joints in the crank case, when the re-assembling of the machine and engine should not present any trouble. Such information as I have given is based on actual experience, and if the jobs, in some cases, should be a little too much for an absolute novice to tackle, he will have the satisfaction of knowing how they should be done, and can see that any overhauling he entrusts to local assistance is carried out in accordance with the article and his wishes.

CHECKING IN RELIABILITY TRIALS.

AS trials hon. secretary of a motor cycling club, the question of checking in reliability trials, to which I have given considerable attention, is one I also feel sure must be of interest to a good many others in the same position. In the old days the winner of a reliability trial of, say, 100 miles was usually the rider who accomplished the journey with the least number of involuntary stops and in conformation with the rules.

Now that the reliability of a motor cycle is so well established it is necessary to adopt other means of finding a winner, and we naturally turn to the system of awarding marks for running closest to schedule time. The usual method of doing this is to allow competitors to synchronise their watches with that of the timekeeper (and checker, if any) and take their own times. This method is unsatisfactory, inasmuch as it is very unlikely that a competitor's watch will keep accurate time with that of the timekeeper.

Now we come to Mr. Scriven's system. It is a well-known fact that a motor cycle rider of real repute makes a practice of running almost to a fraction of a second when competing in a reliability trial, and, assuming for the moment that he could do so, and was suddenly called upon at any point to stop and produce his watch, he would lose an appreciable amount of time in slowing up, dismounting, and producing his watch, with the result that the time at the moment of inspection would be at least several seconds later than that at which he timed himself to arrive. On the other hand, a rider who was not so careful, and who would have passed this point at, say, ten seconds before schedule, would perhaps be credited with having lost no marks. Will Mr. Scriven kindly explain how he overcomes this difficulty, and for which I abandoned the idea? I may be accused by some of labouring on a point which is unworthy of consideration, but the winning of a reliability trial is in some cases only a matter of seconds between the competitors, and those who have had experience in organising long distance reliability trials will appreciate the difficulty.

D. E. A

EASTER MONDAY BROOKLANDS EVENTS.

THE following events will take place on Easter Monday at Brooklands:

EASTER MOTOR CYCLE HANDICAP.—Open to all classes of motor bicycles under 500 cc. cylinder capacity.

SPRING MOTOR CYCLE HANDICAP.—Open to motor bicycles fitted with engines with a cylinder capacity exceeding 500 cc. but not exceeding 1,000 cc.

The entries, fees for which will be 10s. 6d. each event, close on March 17th. Prizes will be: First prize £19, second prize £5, or a cup at option.

To encourage amateurs to compete at Brooklands the Brooklands Automobile Racing Club has decided to draw up a rule to this effect: "Motor cycles fitted with drilled cylinders or with auxiliary exhaust ports, whether covered or not, are not eligible to compete in motor cycle events." This rule will also encourage the use of standard pattern engines.

THE LONDON-EDINBURGH RUN.

SOME new regulations appear in the preliminary announcement concerning the Motor Cycling Club's annual London-Edinburgh run which should serve to make this classical event still more popular. The date is May 13th and 14th. The start is to be at 9 p.m. on Friday, the 13th, instead of ten o'clock as in previous years. The route has been altered from Newcastle-on-Tyne, and competitors will this year travel *viâ* Jedburgh and Dalkeith. The distance is fifteen and a half miles less, and threequarters of an hour less is allowed to cover the total distance, so that the average speed for the journey is about the same as last year, but the new route is rather more difficult. The earlier start and the time knocked off will ensure riders reaching Edinburgh much earlier, and the late starters and unfortunates should appreciate this. The new route will prove an interesting change for seventy-five per cent. of the members who have already won L.-E. medals.

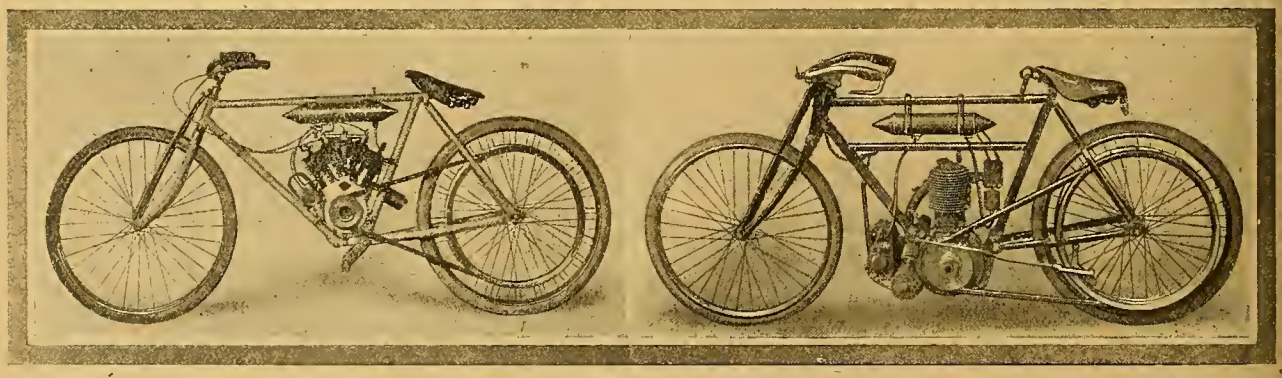
The fifteen minutes ahead of schedule rule has been retained. Some riders do not favour this regulation. Last year it will be remembered that many competitors were disqualified owing to being more than fifteen minutes ahead of their minimum schedule time at some point on the journey, and much grumbling was the result, although the rule was quite clear.

Meal coupons will again be used, as they were found a great boon last year.

Entries close at ordinary fees on April 27th; double fees will be accepted up till May 2nd.

THE LIMIT OF WEIGHT REDUCTION.

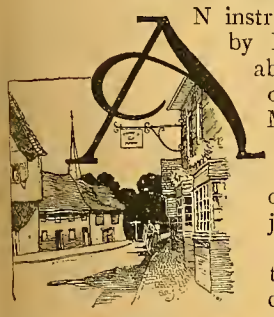
TWO standard makes of motor cycles—a lightweight and a heavyweight—are depicted in the accompanying illustrations stripped of every superfluous part to lessen weight and wind resistance for short distance speed events. The photographs are instructive, as showing the amount of accessories and parts demanded for touring purposes. In their "bared" state the machines are but two-thirds of the weight of the standard model, and are very handy and easy to manipulate. A certain section of sporting riders favour this class of mount, and they are frequently come across at important competitions. Incidentally the photographs just prove how necessary it is to separate standard from racing models in hill-climbing competitions, for imagine the immense advantage the rider of one of the above machines has against a competitor on a standard touring model weighing 40 or 50 lbs. more! In some competitions all have been jumbled together on the officials' supposition that the lightweight racer would score on time and the heavyweight on formula. This may be so to some extent, but a special competition machine would beat a heavy standard nine times out of ten on formula and on time. The chief reasons are because it is so difficult for the comparatively sluggish heavyweight to pick up speed, and especially on a gradient, whereas the nippy lightweight is in full flight before many yards are covered. There is also wind resistance to take into account, and this is far more important than is generally supposed. Last year's competitions demonstrated the futility of amateurs competing on their touring mounts against trade riders on specially built competition machines, and *The Motor Cycle* campaign against "specials" and urging standard machines in competition will no doubt have its effect in 1910 hill-climbs.



SPORTING MOUNTS FOR SPEED EVENTS.

A Moto-Reve Lightweight. A light T.T. Triumph.

Preparations for the Tourist Trophy Race.



AN instructive lecture was delivered by Mr. F. C. Bagshaw on the above subject before members of the Harrogate and District M.C.C. The lecturer was a competitor in last year's event, so that he is well qualified to dilate on the subject referred to.

At the beginning the lecturer mentioned that the ten days he spent in the Isle of Man whilst practising for the 1909 T.T. Race was one of the most delightful and at the same time the most strenuous holidays he had ever experienced, and he advised all motor cyclists who had the time to spare to enter for the event. He went on to say that he considered the last race proved the superiority of single-cylinder motor cycles. His advice was that T.T. machines should not be too lightly built (for preference the weight should be slightly in excess of the rider's), that machines should have a short wheelbase, low saddle position, and wide handle-bars, a large petrol tank with big filler cap, automatic lubrication, together with ordinary hand pump, and special care should be taken that the mudguards are firmly fixed. The tyres should be specially affixed to the wheels by the tyre maker, and the competitor should see most carefully to such parts as belts, chains, and brakes (the shoe brake on the front wheel he does not like, but, if possible, he advised fitting an internal expanding brake in conjunction with the others). Even the saddle should be carefully selected, and the silencer must on no account cause back pressure.

Suitable Apparel for Racing.

For clothing Mr. Bagshaw pinned his faith to good warm woollen vests and pants next to the skin, also a woollen shirt, thick socks, strong riding breeches with leggings, a leather waistcoat with sleeves, ordinary cloth coat, and warm thin gloves, a good body belt, strong boots, and a pair of mica goggles.

Personal training should commence at least three months previous to the race, but before commencing a strict medical examination should be first taken. Then should follow a cold plunge first thing in the morning—not, however, to be taken straight out of bed, but rather allow the body to cool a little. Dumb-bell exercise should follow for no more than a quarter of an hour, taking particular care that the breathing is attended to. After breakfast have a short spin, and then attend to the ordinary work of the day. At night another spin, a light meal, exercise for another quarter of an hour, then early to bed. Very little or no tobacco or intoxicants should be touched; plenty of cold water is recommended, and a hot bath once a week.

When practising on the course commence by going round two or three times quietly, and then once at a fast pace. Return to the hotel for breakfast, then carefully consider all the points of the course and what happened during your first ride. Each day's practice will find you increasing both your speed and distance. Do not ride much during the day, or you will have a tendency to become stale. About three days before the actual race overhaul the carburetter, magneto, valves, and bearings; see that wheels are in alignment and properly lubricated; attend to piston rings, etc. Mr. Bagshaw, of course, does not mean this to be the only supervision, but this particular supervision must be most carefully taken.

The lecturer considered the physical strain of the race far greater than the mental strain.

The Discussion.

Mr. Atkinson then asked the lecturer the following questions: What relation of bore to stroke he considered best? Did he like belt or chain drive? In Mr. Atkinson's opinion the question of valves was most serious. Did Mr. Bagshaw favour a two-piece valve, and what sort of sparking plugs?

Mr. Fawcett wished to be informed upon the question of drilled pistons, and as to whether water cooling was an advantage.

Mr. Fortune asked whether it was advisable to eat much meat whilst training.

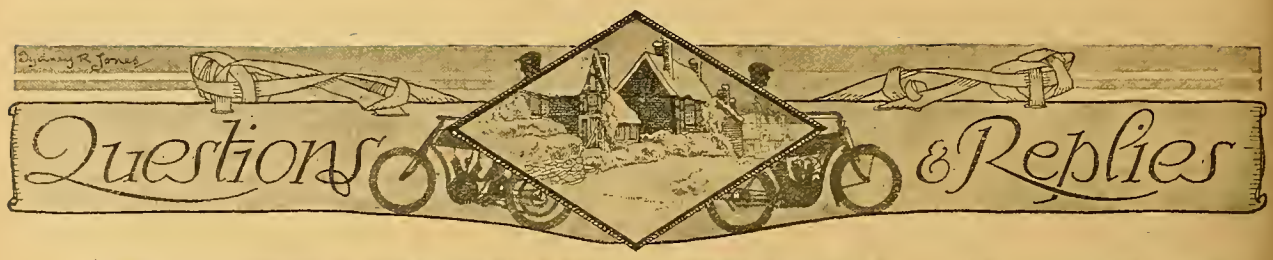
In replying Mr. Bagshaw said that he favoured an increase of stroke over bore, but only to a matter of not more than ten millimetres. He rather fancied belt drive, but thought on a wet and muddy day the slowest chain-driven machine would beat the fastest belt-driven one.

He had not had much trouble with valves, and was quite satisfied with the ones he was supplied with from a small maker. He favoured two double-pole sparking plugs fitted to one high-tension wire. The drilled pistons were for improving the lubrication, but the drilling must be done by the makers of the engine. Water cooling he did not fancy unless it did not increase the weight of the machine beyond what he had already specified, and that by not making any of the essential parts of the machine weaker. He thought whilst training the competitor should keep to his ordinary good habits with regard to food, etc. The whole race, including practising, boat fares, etc., could not be done for very much under £25.

The T.T. Winner's Advice.

Mr. Bagshaw read a letter he had received from Mr. H. A. Collier, the holder of the Tourist Trophy, which ran as follows: "I am of opinion that the race causes more mental strain than physical strain, and that the strain on the rider is greatly exaggerated, and that a course of dumb-bell exercises to tone up the muscles of the arm and wrist and plenty of fast riding, coupled with the rider's ability to tune up his machine, is really all that is necessary." He enumerates the points which in his opinion are essential to success thus: (1) An efficient and absolutely reliable machine; (2) a certain amount of ability to tune up; (3) correct riding position on the machine, so that the least effort is needed in rounding corners at a high speed; (4) a certain amount of experience in high speed riding on the road; (5) perfect health and fitness; (6) plenty of determination to ride to win and enthusiasm.

Mr. Bagshaw was heartily thanked for his very able paper, which was carefully followed by the members present.



A selection of questions of general interest received from readers and our replies thereto. All queries should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, E.C., and whether intended for publication or not, **must be accompanied by a stamped addressed envelope for reply.**

Fitting a Small Sized Tube.

Is there any risk in putting my 2in. inner tube inside a 2¼in. new cover and rim? What effect would it have on patches that may be put on? —R.A.

It would not be advisable, except in a case of emergency, to put a 2in. tube into a 2¼in. cover, as it would stretch the tube to an abnormal extent, and facilitate punctures.

Belt jumping the Pulleys.

I have a 3½ h.p. Ariel, to which I have attached a sidecar, but I am annoyed with the belt jumping off. I purchased a Whittle belt, thinking that it would be an improvement, but instead, the belt flies off more frequently. I have an automatically variable pulley and free engine. Please advise me what to do.—D. I.

Either the pulleys are not true, or are out of line, or the belt does not fit the pulleys. Examine the pulleys carefully and see that they are not excessively worn, and that the correct angle of 28° is maintained with both, then there should be no trouble with the belt.

A 7 h.p. Bicycle for Sidecar Work.

Regarding the purchase of a 7 h.p. V.S. for solo and sidecar, how do you class it among the other powerful machines on the market? I want to be able to negotiate north side of Kirkstone with 12 or 14 stone passenger. Can one start engine with road wheel on the ground with the V.S. gear? and is the hub reliable and efficient? Does a 7 h.p. chew up tyres tremendously? What is the particular danger of a rigid side car at corners and on a cambered road? Does it upset?—H.W.D.

The machine in question should suit you admirably; it is one of the best powerful machines. Yes; it is one of the good points of the V.S. gear that the engine may be started by means of the pedals with the rear wheel resting on the ground. It is well made and reliable. Naturally, a 7 h.p. wears out the tyres more quickly than a 5 h.p. The secret of long wear is to obtain a tyre sufficiently large in the first instance. There is no danger with a rigid sidecar when turning corners if you take the corners at a reasonable speed, unless, of course, the sidecar is empty, when you must be more careful. On cambered roads the front wheel has a tendency to go its own way, but this is easily corrected.

Gear Ratio.

(1.) For maximum speed what gear would be most suitable for my 5-6 h.p. Bat-J.A.P., magneto, 26in. wheels? The engine is fitted with a.o.i.v., and is 1909 type, belt 1in. Would 3 to 1 be too high, or could I go a little higher? (2.) The best gear for touring purposes? I want the machine to climb all hills. (3.) I have never driven a magneto machine before. Can you kindly give me particulars as how best to control it?—J.B.O.

(1.) If you have an adjustable pulley try 3 to 1 for speed, and experiment with a slightly lower and higher gear ratios. 3½ or 3¾ to 1 (depending on your weight) would be more suitable for general purposes. (2.) This question is mainly answered by the above. Use an adjustable pulley, and you can then set your gear to more or less what you please. (3.) When driving a magneto machine you need not pay quite so much attention to regulating the spark. Leave it advanced for all ordinary purposes and control the speed by the throttle and air levers.

A Proposed Tour on the Continent.

(1.) I am thinking of taking a tour in France this spring, starting from Bordeaux, and thence working across to Avignon, and possibly on to Italy. I should be greatly obliged if any of your readers could give me any information as to the roads, or any route they may perhaps have taken in this neighbourhood. Would the journey over the Cevennes be impracticable for a 1909 3½ h.p. Triumph with sidecar and ten stone passenger? I have no objection to occasional pushing, but would not attempt the Cevennes if it means too great a waste of time. (2.) Would joining the A.A. or M.U. simplify the difficulties with regard to introducing myself and my machine into France and Italy?—J.S.M., Oxford.

(1.) Personally, we have had no touring experience near the Cevennes, which, we understand, are not very severe, but over the Italian passes you would have difficulty. In the first place, they are only open during June, July, August, and part of September, and will in consequence be closed to you, so we are afraid the only way of going would be along the Cote d'Azur. The machine would take all ordinary gradients, but it would not tackle such passes as the Little St. Bernard without a two-speed gear, as here you have sixteen miles of an average gradient of 1 in 12. Altogether we should advise you not to take the sidecar if you can manage without it. (2.) Yes, join either the A.A., M.U., or the A.C.U., the touring departments of which will give you the fullest information regarding the roads, and will also enable you to get your machine into France and Italy free of duty.

What is a Free Engine?

Please tell me what is meant by a free engine and a three-speed pulley. Does a motor cycle with a free engine start straight off, or do you have to push it for a certain way just the same?—C. V. H.

A free engine is a device for disconnecting the engine from the road wheels, so that the former can be run independently of the latter. A three-speed pulley is one of the expanding and contracting type operated by a lever which gives three different ratios, and consequently three different speeds. A motor bicycle fitted with a free engine will start from standstill after the engine has been started in the first place.

Repairing a Leaky Tank.

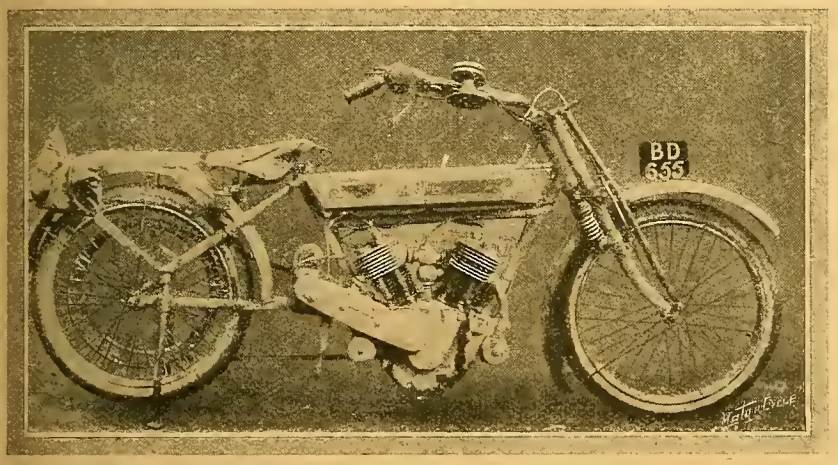
I have been greatly troubled of late through a leak which has appeared at the junction of the petrol cock with the tank. I have tried all means of preventing this that I can think of. I have tried tightening the cock, have used leather washers and lead washers, but in every case the experiment has failed. Could you advise me as to any other method of dealing with this inconvenience? I have been told that a new tank is the only thing which will remedy the defect, but can scarcely believe this.—H.C.A.

A temporary cure on the road is to wrap string around the defective joint thickly smeared with soap. The leak probably takes place at the union, which has been strained, and any repairer should be able to solder this efficiently. If, however, it is a needle valve, and the leak is due to the seating not being true, it means sending the tank to a tank maker's and letting him take it apart, as there may be no other means of reaching the seating for repairing purposes.

Running with Valve Partially Raised.

(1.) Does it strain an engine riding with the exhaust valves partly lifted, in order to go slower? (2.) I am getting a 7-9 h.p. machine, and am afraid of not being able to go slow enough in traffic. Would it be satisfactory if I had two exhaust valve lifters, and so was able to lift one valve entirely and run on one cylinder? Also would it injure the machine in any way?—F. C. M.

(1.) No, but it tends to burn up the valves or cause them to need re-grinding more frequently than would be otherwise necessary. (2.) If the machine in question is fitted with mechanically-operated inlet valves, there should be no difficulty, provided the carburetter is properly adjusted, in travelling slowly. It is not a matter of very much difficulty to adjust the exhaust lifter so that it will lift one valve before the other, so that one cylinder is cut out, but, of course, it is far more satisfactory if you can arrange it to allow the machine to travel slowly with both cylinders firing regularly.



6 h.p. twin-cylinder Clyno, with Stevens m.o.i.v. engine. This machine made a non-stop run in the Quarterly Trials, obtained full marks on Dashwood and Rectory Hills, was ridden 80 miles to Uxbridge the day before the trial, and 80 miles back the day after, all without the toolbag being opened. When one considers the atrocious condition of the roads the merit of this performance may be appreciated.

Difficulty in Starting with the Handle.

I have recently had a Roc conversion set fitted to my 1909 Triumph, since when I have been unable to start the engine up, except by letting in the high gear and running alongside. When I revolve the back axle, no matter how fast, it stops directly I drop the valve. It is quite impossible to overcome the engine compression. I have tried injecting paraffin in liberal quantities, but all to no purpose.—B. F. C.

First of all, to test whether there is anything binding in the gear or the brake band rubbing, remove the belt and try turning the live axle. If this is an easy matter, it proves that engine stiffness is your difficulty. If after injecting a good dose of paraffin through the compression tap the engine is still stiff, we can only conclude that you are using lubricating oil which is altogether too thick for the cold-weather months. An injection of paraffin along the hollow crankshaft would partly remedy matters.

Gear Ratio for a Lightweight.

I have a 1¾ h.p. Clément-Garrard motor bicycle on Chater-Lea frame. This machine I have modernised by fitting handle-bar control and several other accessories, including a large and heavy tool kit. Probably owing to the extra weight, the engine does not pull so well as formerly. Compression is excellent, and will bear my full weight—ten stones—on the pedal for two minutes. The diameter of wheels is 28in., while the diameter of the belt rim is 18in. What gear ratio should I obtain by substituting a belt rim of 19½in. on the back wheel, and would this reduction be sufficient to effect a marked improvement in running up hills and on the level?—M.A.

We should say that the trouble is due to the gear being rather too high. With a 3in. engine pulley the 19½in. belt rim would reduce the gear to about 7½ to 1, which would be a more suitable gear for so small an engine.

Concerning a Lady's Mount.

(1.) What do you consider are the most important features that should be possessed by a lady's (drop-frame) lightweight motor cycle? (2.) Could you give me a list of the various makes of ladies' motor cycles? (3.) Are 2in. tyres advisable for a lightweight?—M. B.

(1.) Ample protection of the lady's skirt from mud and grease from the belt or engine; means of preventing the engine being shielded in any way from the draught of air which cools it; also light weight, ease of starting, efficiency, and comfort. (2.) A list of ladies' motor cycles was published in "The Buyers' Guide" issue of February 7th. (3.) Yes, on account of increased comfort and freedom from trouble.

READERS' REPLIES.

Engine Not Responsive to the Throttle.

I think the following may help "A.L.L.S.": If he will thoroughly clean the gauze in the petrol strainer of his Lagonda it will probably cure his trouble. Very great care must be taken in screwing up the flange to ensure a petrol-tight joint. I found a No. 10 jet and 21 choke tube give very good results with a 10 h.p. Lagonda, and shall be pleased to give him any assistance, as I know these machines well.—H.

Engine Stiffness and Knocking.

In reply to question in your issue of the 7th inst. *re* engine stiffness and knocking, from my experience of both a 1908 Roc and a 1909 Humber I can give the following tips. Turn engine till inlet valve opens. By letting air escape this allows paraffin (I use petrol) to run in more easily. If exhaust valve is open the paraffin of course simply runs out through it. Lean machine over to left side, which allows the paraffin to run over the piston, and while doing so apply a few drops of the paraffin or petrol to the gear box. Then lean machine a little to the right side and turn engine by pulling the belt forward, which causes a slight compression in the cylinder, and so forces the petrol down to the rings. When a routine practice is made of this one does it unconsciously in a few moments, and the engine will be found to start as easily as if it were hot. Remember to oil the band brakes of gearbox every day or two. Cylinder or cycle bearing oil will do, but it loses its effect much sooner, I find, than sperm oil. Five or six drops under the high gear band are sufficient; more causes the slip which follows to continue too long. The frequent application of petrol when starting up washes away this oil gradually, and it should be renewed every day or two. Petrol is better to use than paraffin because it dries up sooner, while the frequent use of the latter makes a mess, and you may have the oil splashing on to your clothes. It is very important that the little push piece in the end of the live axle should be glass hard and perfectly smooth as to its inclined face, otherwise it will get grooved irregularly, and so interfere with the perfect application and release of the band brake. Excess of thick oil in the crank case causes stiffness quite independent of gumming, as I have found on dismantling the engine. I found the flywheels so stiff to turn that I thought the bearings were jammed, and was profoundly thankful to find that an eggcupful of paraffin poured in allowed them to revolve with freedom. Therefore use thin oil. To prevent knocking shut off almost all air on hills. Adjust level of petrol till you can give all air at high speeds on stand with a little more than half throttle. Fit a powerful coiled spring midway along the rod which operates high gear and you will not have to be constantly tinkering with the brake adjustment.—A. MACINTYRE, M.B. Ch.B.

Hints and Tips for Motor Cyclists.

By Road Rider.

CHOKE TUBES.

335. In adjusting a carburetter the choke tube is quite the most important accessory, yet many riders essay their adjustments without possessing this spare. Properly adjusted, a motor cycle carburetter should increase the speed of the engine perceptibly from the first fraction of throttle lever motion to the last, and should increase the engine revolutions smoothly as it is opened out. Many carburetters, as adjusted by their owners, give jerky gradations of power and speed, while the last third of the throttle opening makes no apparent difference to the engine. It should first be noticed that the control slides or pistons or valves work accurately and smoothly; this can never safely be taken for granted. Then the level of the spirit at the jet should be tested. Then a jet tube should be selected which gives easy starting, ample power, and moderate consumption. Finally the effects of choke tubes slightly larger and slightly smaller than the one in use should be tried. A speedometer is often of great assistance in these tests. I have just been tuning up an engine, and found that with the standard choke tube I got forty-five miles per hour on half throttle, and only forty-six miles per hour on full throttle. A larger choke tube increased the pace to fifty-one miles per hour on full throttle, and gave me a more even rise of power and speed throughout the whole range of the throttle.

FLEXIBLE PETROL PIPES.

336. Riders who have suffered from broken or cracked petrol pipes are waxing enthusiastic about the flexible pipes now fitted to some machines. These flexible pipes have much the same strain to bear as the old-fashioned rigid pipes including a triple twist, and practically the whole of the strain is concentrated at the points where the flexible pipe enters the rigid unions. After long use, the flexible pipes must inevitably give trouble at these points. I am inclined to think that it is possibly unwise to rely exclusively on a single flexible pipe, while there is no doubt that they form most desirable spares for long tours or trials, and especially on passenger machines liable to special vibrations.

THE NEW MAGNETO POSITION.

337. The new position of the magneto, high up at the back of the engine, will in certain instances create trouble through inadequate lubrication of its drive. No trouble need be apprehended with regard to the drive, as the chain links, or teeth if pinions are employed, will carry ample lubricant upwards with them, but on one or two machines employing a gear drive it is not too certain that the bearings of the shafts of the pinions will secure sufficient oil, though the teeth are safe enough. I have already seen one or two machines with which trouble is inevitable, unless small spring lid or helmet lubricators are mounted in threaded holes drilled over each shaft bearing, and receiving occasional attention from an oilcan.

MAGNETO CONDENSERS.

338. I have found some variation of efficiency in the condensers of high-tension magneto machines. Whereas several machines will run literally thousands of miles without the platinum points being given any attention another sample may require to have its points frequently cleaned, and tapped or filed flush. This difference is undoubtedly due to a faulty or broken down condenser, and in case a very poor condenser has been supplied, or the symptoms point to a broken down condenser, the magneto should be sent to the makers for attention. The engine speed is extremely susceptible to the condition of the platinum points.

LEAKY INLET UNIONS.

339. I often notice machines with serious air leakages in the inlet system, especially in the case of a.o.i.v. twins, when the riders are hardly to be blamed, as the arrangements used on some engines for attaching the domes and pipe are mechanically execrable, and it would puzzle anybody to maintain air-tight joints. Such leakages have, however, very deleterious effects on the running of the engine. The makers of certain patent carburetters used on cars occasionally refuse to fit their carburetter unless the owner agrees to allow them to supply better inlet pipe attachments. Special care is needed at two points on many motor cycle engines, viz.: (1.) To drive the inlet valve dome well down on the ground shoulder of its seating; with a twin it often happens in careless refittings that the dome of one valve is an eighth of an inch off its shoulder. (2.) At the unions between the inlet pipe and the elbow projecting from the dome. Leaks occur between the end of the pipe and the nut. A felt washer placed inside the nut, for the end of the pipe to butt up against, is a good cure.

SPARKLETS.

Stanley Show Donation.

The directors of the Stanley Show, Ltd., have for the second time sent a donation of one hundred guineas to the Cycle and Allied Trades' Association.

Catalogues Received.

We are in receipt of an artistic calendar from Mr. W. W. Bannister, motor engineer, Maidstone, the manufacturer of the Unecar recently described in *The Motor Cycle*.

The 1910 catalogue of the Clyno Eng. Co., Thrapston, is to hand. This contains illustrations of the single-cylinder 3 h.p. Clyno and the twin-cylinder 5-6 h.p., also the adjustable pulley and stand marketed by the same firm. Copies can be had on application to the above address.

A well illustrated catalogue of the Bat motor cycles is just to hand, containing excellent half-tone engravings of the famous Bat machines, which are built for both road and track. In reviewing this list, it is interesting to note that it is now seven years since the first Bat motor cycle was introduced. It is one of the few motor cycles of which the frame is sprung as well as the forks. This, combined with its unique method of magneto transmission, makes it one of the most interesting motor cycles of the day. Copies of this catalogue will be sent on application to the Bat Motor Mfg. Co., Kingswood Road, Penge, S.E.

The Transmission Question.

Chain transmission scored very heavily in the last Quarterly Reliability Trials. Five out of the first eight places were taken by one Scott, one Phelon and Moore, and three Indians, all chain-driven motor bicycles. All the above-mentioned machines were fitted with chains of Renold manufacture.

Rubber and Canvas Belts.

Rubber belts have been adopted as standard by most motor cycle manufacturers for a number of years, and it will be interesting to note that the grooved pattern rubber belt, of which the manufacturers of the Shamrock-Gloria belt claim to be the originators, was first invented and made as far back as 1903. The Hanover Rubber Co. inform us that a provisional patent was taken out by them for a grooved rubber belt, but as it was allowed to lapse the grooved pattern has been adopted by several other makers. We are informed that the grooved rubber belt was first taken up in England by the Triumph Cycle Co., Ltd., who first fitted it in 1904.

The Home Garage Sidecars.

The New Mona Cycle and Motor Co., Mona Works, Barrett's Grove, Stoke Newington, N., have acquired the sole rights of manufacturing the Bramson home garage sidecar, which was recently described and illustrated in *The Motor Cycle*.

The Exchange Business.

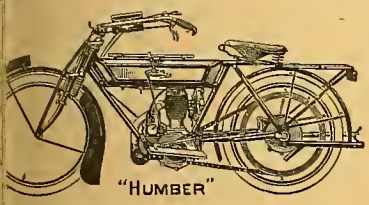
Motor cyclists in want of a second-hand machine cannot do better than visit Messrs. Wauchope, 9, Shoe Lane, E.C., or correspond with them. A few facts about the business may be of interest. In the first place, no less than fifty new machines of the leading makes are kept in stock, while there are as many as 150 second-hand machines from which to make a choice. After a customer has bought a second-hand machine he is allowed fourteen days in which to return it or exchange it for another if it is not satisfactory. When a second-hand machine and cash is to be given in exchange for a new one, a reply is sent from the firm stating the price offered for the old machine, and under no circumstances, unless the machine has been misrepresented, is a price allowed lower than that originally stated. Messrs. Wauchope have built up a big business.

IONEY TALKS.

it cash offers. Our stock of new Humbers is exhausted, and we have only a limited quantity Write for full specification of these ideal sidecar s, and we will let you into the secret of buying chines at second prices.

IUMBERS FOR EASTER.

ne of these 1909¾ two-speed Humbers, fitted with et Sidecar, and you can pass on the road cars £500. These are started by handle; you get in dle, put in the clutch, and you glide gracefully Can be driven slowly in traffic and take hills with pecial price for the combination. Remember, de- om stock.



"HUMBER"

received from makers, a few

Auxiliary Exhaust Release.

ANOTHER of those unfortunate rulings which, unless recalled, will undoubtedly go a long way to retard progress has just been issued, this time by no less an important body than the Brooklands Automobile Racing Club. We refer to the rule regarding the Easter events at Brooklands, which states, "Motor cycles fitted with ported cylinders or auxiliary exhaust ports (whether covered or not) are not eligible to compete." Naturally, the B.A.R.C. has issued the regulation with good intent, the idea being that it will encourage the use of standard machines, and will give the amateur a better chance of winning than formerly. With this we agree to a great extent, but the B.A.R.C. has unconsciously hit rather hard against at least two firms we know of, but probably when the true facts are made known the regulation will be amended. This issue of *The Motor Cycle* contains an announcement and description of the first motor bicycle to be *standardised* with auxiliary exhaust release holes in the cylinder. If all that is expected of it comes to pass, this new departure is likely to be the forerunner of many other devices of a similar nature. Yet experiment and progress in this direction are likely to be hindered by a rule which we are bound to think has been issued without the prior consideration the question deserves. Who knows that additional outlets for the exhaust gases may not be standard some day? The frequency of exhaust valve breakages last year, and the numerous complaints of knocking in the engine, strongly suggested some such desirable improvement. In framing the rule it is highly probable that the B.A.R.C. committee had in mind the exposed holes in the cylinder walls as adopted on some racing machines, the fearful din, and the rider's legs bespattered with oil blown through the additional holes in the cylinder. Such were the conditions obtaining in the case of track racing motor cycles of bygone days, but there is nothing of this kind connected with the engine described on another page of this issue—in fact, one could not tell from a casual inspection that there was anything special about the engine. Nor is there any extra noise caused by the additional outlets for the burnt gases. Obviously, therefore, there is nothing against this type from the point of view of appearance and noise, and now what everyone interested in motor cycles would like to know is whether the exhaust release holes have a beneficial effect on the running of the engine, and how this type of engine compares with the orthodox type, when raced side by side under equal conditions. Unfortunately, on account of the rule referred to, the makers of the engine in question are for the present moment debarred from entering for the Brooklands Easter events and demonstrating the advantage (if any) of auxiliary exhaust ports, although we are assured that it was their original intention to do so. We trust that the Brooklands Automobile Racing Club Committee will quickly see the ill-effect the regulation they have just issued is likely to have, and recall, or at least amend, it before the date of closing of entries for the Easter events.

1200 MILES ON A MOTOR BICYCLE WITH SIDECAR

BY

VINCENT BURROW, M.D.

(The first instalment appeared in our last issue.)

EIGHTH DAY.—Cullompton to Barnstaple, 54 miles.

Having put on the new Shamrock belt, we started at 10.30 *en route* for Dulverton, but had a stop on the road, owing to stretching of the new belt. The best road is not the direct one to Tiverton, which is all hill, but that through Tiverton Junction, which is almost flat. At Tiverton we obtained petrol and oil, and were soon winding our way along the beautiful Exe Valley. This is one of the finest rides in the country. A horse and trap coming from a side road narrowly missed us, and shaved off the fastener of the sidecar lamp. Leaving Bampton on our right, we ran on to Dulverton, and, wishing to see a little of Exmoor, we ran up past the town, but were directed wrong, and had to take a narrow lane with loose stones and deep cart ruts, and almost dark in places from the overhanging foliage, and, to make matters worse, a real Devonshire gradient. I found it impossible to drive up, and had recourse to pushing and occasional use of low gear whilst running alongside. It was a desperately hot piece of work, and we seemed to be never coming to the top. Showering innumerable maledictions on the man who had directed us, we at last reached the summit, and got on to the moor, where we enjoyed a much needed rest. Going down to the town again by another road, we came to such a sudden and dangerous drop that we dared neither to drive down nor walk down with the machine, but, discovering a private road leading down to the town, we took French leave, and hurriedly drove down that way, spending some little time exploring the beauty spots of Dulverton.

Leaving shortly *en route* for Barnstaple, we came to a very steep hill about five miles from Dulverton, so steep that the belt slipped constantly on the low gear, and it required a brisk bit of pedalling to get up. Getting tea at a friend's house at South Molton, and spending about an hour there, we left at 5.50, going down a steep descent at Swimbridge, and arrived at Barnstaple at 6.20 p.m.

All the Devonshire roads so far we had found thick with white and red dust, but the surfaces of the main roads excellent. We had to shorten the belt twice on this day, and noticed just a few spots of rain.

We had intended to motor to Lynton, but were strongly advised to take train, and it was fortunate we did so.

Covered with dust, we motored to the station to enquire as to trains, when, on walking back to our motor, a cabman facetiously remarked, "Cab, sir?"

Porlock Hill, Lynton and Minehead coaches descending.

NINTH DAY.—A Visit to Lynton and Lynmouth.

The morning proved bright and frosty. Leaving at 7.30 a.m., we took our first ride by train since starting from home. The railway is quite a toy affair; the gauge is only 24in., and the small wheels bring the coaches very near the ground. The train is a triumph of the engineering art. It winds in broad S curves round the sides of the mountains, and even then in places the gradients are stiff. Lynton station is high above the town, and there is a steep descent to the latter, also thence a steeper and winding path to Lynmouth. This is one of the beauty spots of this coast. The walks by the rocky river bed, shaded from the sun by the luxuriant foliage, must be taken to be appreciated. No description of mine could portray their beauty. All the hotels in the town seemed full of visitors and tourists. We spent nearly the whole day by the river, walking to Watersmeet, and also seeing the harbour and noting the cliff railway. We returned to Barnstaple in the evening.

TENTH DAY.—Barnstaple to Tavistock, etc., 75 miles.

Leaving at 10 a.m., we ran through to Bideford (close to the coast), and then on to Clovelly. At the

Miles on a Motor Bicycle with Sidecar.—

pf the hill we left the N.S.U. and walked down winding path, and finally down the steps leading ie village.

Lovelly has a beauty of its own, and is more ait than Lyn- ia. The High et is traversed eans of steps vl with cobble r, and is, I n, unique. A ater from asea and Ilfra- ne was just ping anchor e we arrived. eling some u here, we ially re- rd on our y o Tavistock ilkhampton, abn, and ueston, where r is a steep l through the vn which we oated on low speed. This part of the county ve hilly, and no end of lubricating oil is required. viock was reached at 6.30. We drove straight oh to Mary Tavy, a village four miles out, to sne friends, and stayed h hem till dark. Re- ni , we took the wrong d, and encountered so ep hill that my passenger l walk. The motor, , s sulky, and very hard st , and misfired badly. wer, 10 o'clock saw us k t Tavistock, where we ye the night.

Lynton and Lynmouth from Summerhouse Hill.

E ENTH DAY.—Tav- oc to Escott, 52 miles.

Th next day, after oiling , discovered the cause th motor's erratic be- vio was pitting and ick ing of the platinum int of the contact breaker. so filed and adjusted m, nd the motor was in go trim as ever. There to steep hills on to rtm or. A herd of cows ilt our climb on one of m, nd my passenger had di ount and walk part the ascent. The second w were climbing well, en he gear went wrong, I made a hurried dis- unt Fortunately, nothing worse had happened n tat ; owing to the strain of starting on such steep dic ts, one arm of the stirrup working over the set-screws had bent and jumped the screw. I took the stirrup off and bent it back into place, and the gear was again perfect.

We started up on the 1 in 10 gradient, and passed to the top. The prison and Princetown we saw in the distance, and, being ready for breakfast, we got out our basket and made our meal amongst the yellow gorse and purple heather in the kindly rays of the sun. At Dartmeet we stuck on a very steep hill, the surface being very loose. This meant another walk for my passenger and two more attempts on my part before succeeding in driving up, and then with hard pedalling. Stopping on a less severe portion, I essayed to start off with my passenger, but it was fruitless, as the engine stopped each time I put the low speed in. I went up alone, therefore, and waited at the top nearly half an hour for my passenger, who found it hard work even to walk up. All this took time, and it was now past two o'clock. At New Bridge Hill, the gradient of which must be something terrific, the brakes, although locking the back wheel, failed to hold the machine, which shot forward at an alarming speed, and wearing a beautiful flat on the back tyre. The hill being winding and evidently very dangerous, I quickly decided to steer for the hedge and bank, and managed to strike same with the front corner of the sidecar. The cane-work was bashed in, but it drew us up promptly, and with no injury to ourselves or the front forks. We then wheeled the machine down the hill with low speed in gear, compression on, and hand brake applied, and even then had difficulty in holding it back. This hill is, I consider, the most dangerous we came across in our tour, and yet there was no sign of a warning board or triangle—in fact, I saw none on any part of Dartmoor. I heard in Ashburton shortly after that a day or two

Entrance to the close of Sarum, North Gate, Salisbury.

1200 Miles on a Motor Bicycle with Sidecar.—

before two cars came to grief on the identical corner where we took the hedge. One burst into flames, and the other, in endeavouring to draw up to render assistance, crashed into the first. After this episode we had an uneventful run into Ashburton, arriving there at 2.55.

Filling up with petrol, and after quaffing a large glass of cider, we left about 3.30, and came upon some excellent roads, and these were almost flat besides. Two miles from Chudleigh the back iron supporting the footboards struck some large obstacle on the road and wrenched off the boards. These I got put on again at Chudleigh. Meanwhile we visited the rocks, glen, and caves, all worth seeing, and had tea under the shade of the apple trees at the glen.

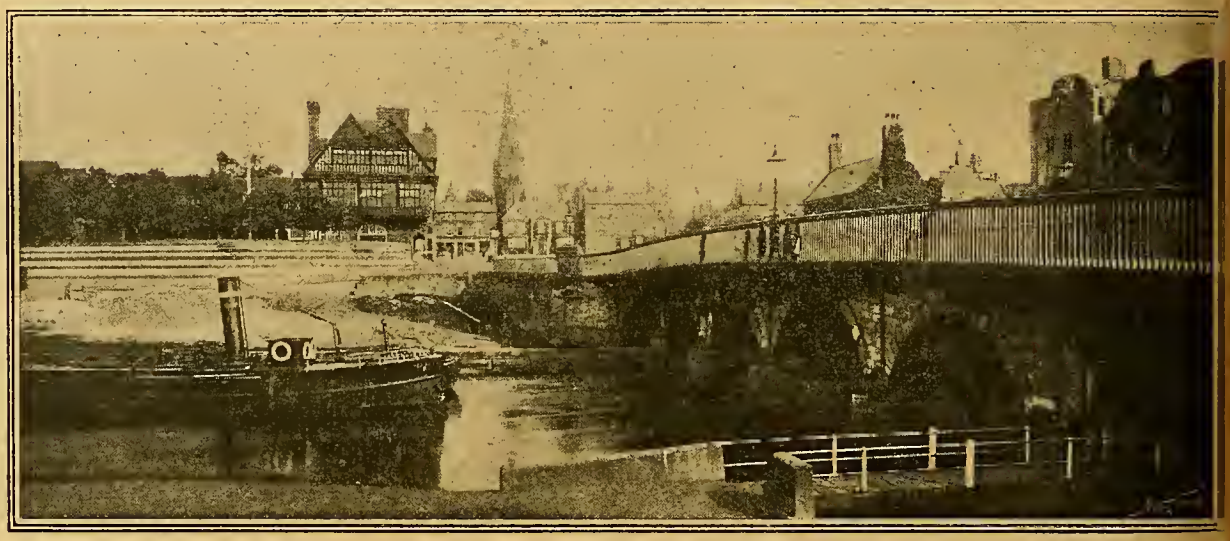
Passing through Exeter at 6.30, we had two bad skids on wet tramlines. In each instance the skid ended in my cycle falling over towards, and locking against the side of, the sidecar, jamming my leg between the two and pinning me helpless until my passenger got out and pulled the motor upright. Past Heavitree we encountered a long ascent, followed by a similar descent. Near the village of Escott we happened to meet the county surveyor, and, hearing there were unrolled stones further on, we decided to stay where we were. We were comfortably housed at the Fairmile Inn (one of the P.R.H.A. houses), were well attended to, and found the tariff exceedingly moderate.

TWELFTH DAY.—Escott to Bournemouth, *via* Salisbury, 109 miles.

It was quite a change to wake up and find ourselves in a quiet village after the bustle of the towns we had previously stayed at. The weather was still magnificent, and, leaving in good spirits, we ran into Honiton. Then we had several miles of uphill to climb, which, although not steep, made the going rather slow. Then through Chard to Yeovil, where we took some petrol, and where I at last happened on a garage where I had the choice of Price's or Vacuum oils. Then on through Sherborne and Shaftesbury to Wilton, the outskirts of Salisbury, the N.S.U. all the time r ning with the regularity of a locomotive. Getting at Wilton, we ran into Salisbury at four o'clo Another gallon of petrol, and we started off Bournemouth *viâ* Ringwood and Christchurch. T road is almost flat, and in places very pretty. Arr ing at Boscombe, we found the tramlines so w watered that, bearing in mind the previous skiddi propensities, we crawled along on low gear until came across a suitable hotel, where we put up, a after a wash and change took train to Bournemou itself.

THIRTEENTH DAY.—Bournemouth to Brac ley, 114 miles.

Leaving about 7.30, we were soon running throu Christchurch, and thence had an uneventful run ba to Salisbury, and, passing through, we were soon up the Andover Road, keeping a wary look-out for poli traps. The road was inches deep in loose, sha



Trent Bridge, Newark, familiar to London-Edinburgh riders. The castle, the ruins of which may be seen on the right, was demolished by Oliver Cromwell.

flints, and momentarily I expected tyre troubles. Su enough, about four miles from Andover my front cov and tube were cut through by a sharp flint. As had noticed at Stroud a week before a very decid bulging in one part of the front cover, which h gradually increased in size, and now barely cleared t forks, I thought it would be a good opportunity to p on the new cover which I carried tied on to the ba of the sidecar. Alas! I little knew what I h essayed to perform. The fierce rays of the su from which there was no shelter, beat upon me as, wi coats removed, I proceeded to take out the whe having previously searched in vain for a piece of wo or stone to put under the crank case, in order to rai the front wheel from the ground, and having at l to jack it up with my spare petrol tank. The whe came out without much trouble, and I repaired t cut tube, and then tried to get the new cover on t rim. Perspiration poured down my face as at last got one side of the cover on, then the beaded ed had to be cut away to make room for the secur

200 Miles on a Motor Bicycle with Sidecar.—

bolts, and, hardest of all, those security bolts had to be coaxed into their places. Eventually this was accomplished, the tube inflated, and the wheel ready to be put back into the forks. The girders had to come off to get the spindle in, but at last everything was accomplished after nearly two hours' work. Starting off, we passed safely through a police trap, and got to Andover close on two o'clock. Half starving, for our luncheon basket was empty, we ordered a big breakfast, to the astonishment of the restaurant people, who thought we meant lunch, and, having partaken of same and replenished our petrol tank, we turned off the London Road and made direct for Newbury. When just about clear of the town we disturbed the equanimity of half a dozen hens which were strutting about the road. Three of them took to the hedge, but the other three were foolish, and attempted to cross our path. What became of one I don't know; the second dodged under the sidecar; number three, although I did my best to avoid it, pulled my front wheel. Immediately there was a cloud of feathers blown up into my face, and when these had cleared a bit I perceived the hen firmly jammed between the front forks and rays and the rapidly revolving wheel. I turned and said to my wife, "It's a case of sudden death, at any rate," and so we thought. When well clear of the houses I slowed down and stopped, and with some difficulty dislodged the hen, and threw her down on the grass, when, to our amazement, she bounced up and staggered across a ditch into the hedge, where it succumbed. After this incident the ride proved uneventful. The road we had taken proved very good except for one dangerous descent, which we cautiously negotiated with both brakes on. Abingdon was reached at five, and, after having tea, we were soon threading our way through Oxford. Our route now lay direct to Northampton, and proved very good indeed. It is flat, almost dead straight, and the country is well wooded and picturesque. The puncture fiend again visited us four miles out of Oxford; again it was a sharp flint. After a stop to light up we drove, assisted by the light of the harvest moon, to Brackley (Northants), reaching there about eight o'clock. Here we elected to spend the night.

Micklegate Bar, York.

FOURTEENTH DAY.—Brackley to Selby, 156 miles.

Leaving betimes, we encountered a thick, heavy mist, which did not disperse until we had got nearly into Kettering. Northampton was enveloped in fog, and this was the cause of our taking the wrong turning out of the town and finding ourselves hopelessly at sea in narrow winding lanes. We had to make a semicircular detour through rather pretty lanes, and finally struck the main Kettering road after considerable loss of time and trouble. Getting breakfast at Kettering, the mist now rapidly clearing, allowing the sun to exert its power, we ran along the switchback road to Stamford, where we stayed an hour. Having been warned by a passing motorist, we crawled through three police traps on both sides of Grantham, being now on the Great North Road. At Muskham, near Newark, we suffered another puncture. We passed through Doncaster at dusk, and, having lit our lamps, drove in the moonlight the twenty-one miles to Selby, where we decided to stay that night.

FIFTEENTH DAY. — Selby to Newbiggin, 128 miles.

The last morning of our tour was dull and threatening. Leaving at 7.30, our first stop was at the toll bar just out of Selby, the charge being 9d. for cars and 3d. for motor cycles. We had belt trouble, also a broken belt fastener, and halfway to York our petrol tank ran dry. Fortunately, I had nearly two quarts in the spare tin, and poured this into the tank. At nine we entered York, and bought two gallons of petrol. On this day the two-speed gear caused slow travelling by slipping on the top speed, owing, I suppose, to the clutch spring being rather too weak. We had no other trouble, and, passing through Thirsk, had breakfast at Northallerton. We left the latter town at mid-day, and soon got to Darlington, where I obtained and fitted on a gaiter for my back tyre, the rubber tread having worn right away in places, and the canvas being frayed and thinned. Leaving at two, we ran on without a stop to Gateshead, encountering for the first time during our tour heavy rain and a cold headwind at Ferry Hill. Exactly at the end of the high level bridge at Gateshead our tank again ran dry, and needed replenishing from the spare tin. Thence we ran on to Morpeth after yet another skid on the tram-

1200 Miles on a Motor Bicycle with Sidecar.—

lines in Newcastle, filled up with petrol, and arrived home at a quarter to six.

Thus ended a most pleasant tour, during which we covered nearly 1,200 miles, in splendid weather, and, had it not been for the tyres and to a lesser extent the belts, we had practically no mechanical trouble. All the nuts and bolts on the motor were firm and secure at the end of the tour, and the engine behaved admirably. Tyres, as usual, were the chief trouble. The back tyre was a new specially reinforced pattern, yet was practically worn out in the 1,200 miles. The front tyre, which previous to the tour had only done 400 miles, had to be discarded. When will tyre makers give us a tyre with a decent amount of rubber on it? The two-speed gear was severely tested, and without it I am positive we could not have completed the tour, especially in Devonshire and the steep hills on Dartmoor. Except for the slipping of the clutch previously mentioned and the oil throwing, it worked as near perfection as one could wish.

The magneto, too, functioned admirably.

The sidecar proved safe and reliable except on greasy roads and tramlines, on which it is not a practicable vehicle unless the motor cycle be shod with non-skidding tyres, for it seemed to accentuate a skid.

The whole tour was completed on twenty-three gallons of petrol and five quarts of lubricating oil costing roughly £1 8s. and 7s. respectively, or £1 15s. in all.

This works out at an average of fifty miles to the gallon, which I think is not excessive, considering the country we went through, the amount of luggage, and the fact that the engine was a 6 h.p. twin.

Finally, a word of advice to any who desire to tour in Devonshire with a passenger attachment: Have plenty of engine power, strong brakes, and at least two speeds.

OCCASIONAL COMMENTS.

By "IXION."

Steel-studded Treads.

The last Quarterly Trials, according to certain authorities, "sounded the death knell" of the steel armoured tread for motor cycling purposes. Rubbish! It demonstrated the fact that steel-studded treads are worse than useless over frozen roads, but every sane rider of any experience knew this years ago. The steel-studded tread stands exactly where it stood before. It remains the fastest and safest tyre over really dangerous summer grease, upon which it affords an appreciably firmer grip than rubber projections. It retains efficiency as an anti-skid slightly longer than rubber projections, in my experience, because it is tougher in wear. It slows the machine more than rubber projections; it is far more liable to skid on smooth, hard surfaces, such as asphalt or stone paving; it is almost essential for passenger combinations over certain surfaces—I find rubber studs too pliable to hold a fast tricar or sidecar outfit to the path of rectitude over Derbyshire grease, for instance. But it is certainly the last tread in the world to trust to in the January Quarterlies when the roads are like a sheet of ice; and for winter riding generally it is less trustworthy than a rubber tread.

Insurance.

My experience is that the great majority of motor cyclists are totally uninsured with regard to their hobby. I can sympathise with a man of limited capital, who does not wish to burden himself with an annual premium of several pounds, and prefers to trust his £50 machine to his own skill and address, so far as collisions and fire are concerned, the same applying to his own personal safety. But riders should remember that the third party risks are the gravest liability attached to the sport. The most cautious motor cyclist may have the ill-luck to kill or cripple a child or an adult through no fault of his own. When he comes into court, as he is sure to do, he will encounter a tolerably strong prejudice against motor cycling in general; if the victim of the accident belongs to the poorer classes, he will be credited with a fictitious opulence on account of his ownership of a costly machine, and he is very likely to be condemned in damages running into hundreds of pounds, even if not an atom of responsibility for the accident properly attaches to him. Quite apart from rights and responsibilities and prejudices, any motor cyclist would like to be able to compensate, for instance, a poor man whose child had committed suicide under his wheels. Every motor cyclist should carry a third party policy of £500, for which the premium is quite small.

Advice to Club Secretaries.

A good many club secretaries bewail the apathy of their members, and not without cause. A membership of seventy or so produces a most meagre attendance at winter evening fixtures, and during the riding season perhaps only a dozen, on an average, honour social runs by their presence. The first thing to realise is that circulars effect little. Good average attendances are only worked up to start with by personal solicitation. A man who will put a dozen circulars in the waste paper basket will turn out if you call on him and give him a personal invitation. When you have once got him to a fixture, you must ensure him a pleasant evening, or he will not come again. Therefore, be as scrupulous about the character of your entertainment as if you were managing a music hall for a living. Move about amongst the members, and see that the shy souls are brought out and made to feel at home. After a successful winter season, just the same trouble will recur with regard to the summer programme. Most weak clubs err by catering exclusively for one type of rider—their runs are too long and too speedy, their competitions too exacting. At the outset the runs should be short and leisurely, and the novice member or the owner of an old crock should not be left toiling forlornly in the rear of a dust-raising crowd of scrappers. Gradually the distance may be increased, but the pace should always be moderate, the ardent spirits being firmly curbed. When competitions start, the early fixtures should be of an easy character, in which experts and costly machines have no special advantage. Speed judging, paperchases, slow hill-climbs, and the like, are to be recommended, until every member realises that he will never be left hopelessly out in the cold.

A selection of questions of general interest received from readers and our replies thereto. All queries should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, E.C., and whether intended for publication or not, **must be accompanied by a stamped addressed envelope for reply.**

Draining the Crank Case of Dirty Oil.

Attempting to remove the screw at the bottom of the crank case of my machine in order to drain out the dirty oil, I had the misfortune to reak off the head of the screw, aving the body still firmly em- edded. There is now no means of raining out the oil. Does this atter? If so, what would you dvise me to do?—M. W. L.

It would be quite easy for a good mhanic to remove the screw in the crk chamber by drilling it. Cer- tay it is desirable to have a drain pl;, as one ought to empty out the ol oil at least every five hundred ms, and swill the crank case with pa ffin. A noticeable improvement in be running is usually the result.

A Frequent Query.

I have a 3½ h.p. 1909 machine, fitted with an Amac 1910 carburetter and a variable pulley. The gear at present is 4¾ to 1. Would it be pos- ble to use the cycle for sidecar work I lowered the gear? I am a light ler, and should not take a heavy rson in the sidecar. There are ne fairly stiff hills in the neigh- urhood. Does a sidecar strain the otor cycle much?—R. S.

To get any real satisfaction out of a ma ine used in conjunction with a sic ar you need a two-speed gear. On the other hand, in a fairly level co try, if you gear 5½ to 1, you should get fair amount of satisfaction with a decar, though you will not, of co e, climb such hills as Westerham, wh h has a maximum gradient of 1 in .

Respecting a Passenger Attachment.

My mount is a 3½ h.p. 1909 Rex (new in December), with free-engine clutch in back wheel. I wish to go in for a sidecar, or, if more suitable, coupler for a push bicycle. Com- ed weight would be about 18 st. (Which mode of carrying pas- ger do you advise with my chine, which is geared 5 to 1, and ich would be the least strain and iest to drive, and fastest? (*b*) If decar, which type? Have heard tible throws less strain on frame. l this so? (*c*) If you consider two- ed gear essential, could I have e fitted without cost of another tch also?—H. V. S.

(*a*) The best and most popular mode of rrying a passenger is with a side- car. It does not impose any undue strain upon the machine. It is not easy to drive until you are used to it, but, from the passenger's point of view, it is infinitely preferable. (*b*) It is true that a flexible sidecar imposes less strain on the bicycle, but for all-weather work the rigid sidecar is sometimes pre- ferred. (*c*) Yes, a two-speed gear is essential. The best thing you can do is to get the one fitted which is made by the makers of your machine. You may reckon a really reliable two-speed gear will cost you about twelve guineas fitted.

The risk of soldering petrol tanks.

I have a surface carburetter which I wish to remove and solder up in several places, and should be glad to know the best way to do this with- out an explosion. Would filling it with water answer?—G. W.

If this is to be your first experience of soldering a petrol tank, we should advise you not to touch it, but take the tank to a competent repairer. Last year there were several accidents owing to the petrol fumes not having been removed completely. Merely swilling out the tank with water is not suffi- cient; it should be repeated several times, and the tank left out in the open air for about a day.

Low Registration numbers. Lubrication.

(1.) Is there any difficulty in getting my cycle registration number cancelled, and where can I get a fresh low number, a southern English county for choice? My present L.C.C. number plate of six letters and numbers sticks out in front like a signpost when sufficiently advanced to be well illuminated by the lamp, and I want something neater. (2.) How often and how much should I oil (N.S.U. 2½ h.p. twin, new machine), and should I invariably oil when starting for a ride or start- ing on the stand?—F. W. P.

(1.) We are afraid that there are no low numbers obtainable in southern English counties. It would be better to register the machine in Ireland, where you can get probably two figures, if you try counties such as Sligo or Longford, in which case write to the Clerk of the County Council of either of these districts. (2.) After you have ridden the machine for about five miles, inject a pumpful of oil, and then oil regularly and as usual throughout the ride.

Various Interesting Queries.

(1.) Is a plain coil faster than a trembler coil? (2.) Would an ordinary plain coil be capable of sparking at two gaps in series if the points of each plug are made closer than is usual when one plug alone is used? (3.) What advantage is there in having carburetter close to engine—that is, in having a short distance for induction between jet and inlet valve? On my machine (2¾ h.p. with old F.N. carburetter) the mix- ture has to travel about 9½in. be- tween jet and inlet valve. Should I gain much by getting a new pattern carburetter and fitting it so that there is only a short length of in- duction tube necessary? (4.) What amount of opening should I have in my a.o.i.v.? Is ¼in. too much?—W.I.P.

(1.) A plain coil is certainly faster than a trembler coil. (2.) Yes, the coil would do what is required if special double pole plugs are used. (3.) The object is to warm the carbu- retter effectively, so that vaporisation of the petrol is easy in cold weather without the necessity for a special warming pipe. Some contend that a fairly long induction pipe is bene- ficial, as it allows the petrol vapour and air to mingle more thoroughly. (4.) ¼in. is too much; ⅛in. would be more likely to give the best results.

Engine Knocking at Slow Speeds.

My 80 mm. Fafnir engine (accumulator ignition, non- trembler coil, B. and B. car- buretter) has taken to knock- ing at low speeds—a dull pounding knock at each explosion, quite distinct from the sharp knock caused by the ignition being too far advanced. The engine is very slow gathering way, but when it picks up speed and I can give air it stops knocking. Does not knock at speed (ten miles per hour and over), nor up steep hills until slowed down. I have had cylinder off, and there is practically no up and down play in connecting rod bearings. Engine overheats, but knocking occurs when starting from cold, and at all spark positions until machine has gathered speed.—A.F.B.

It is somewhat difficult to say what is the cause of the trouble. First of all, we should advise you to examine the carburetter and see that everything is in order. Very often too weak a mix- ture (*i.e.*, too much air admitted *via*

th· main air inlet) will cause knocking. Secondly, the knock may be a mechanical one, due either to a worn bearing or possibly to one of the flywheels being loose. If the timing of the spark is too far advanced this would cause knocking, and especially if the gear ratio is high.

Uneven Running in Two Cylinders.

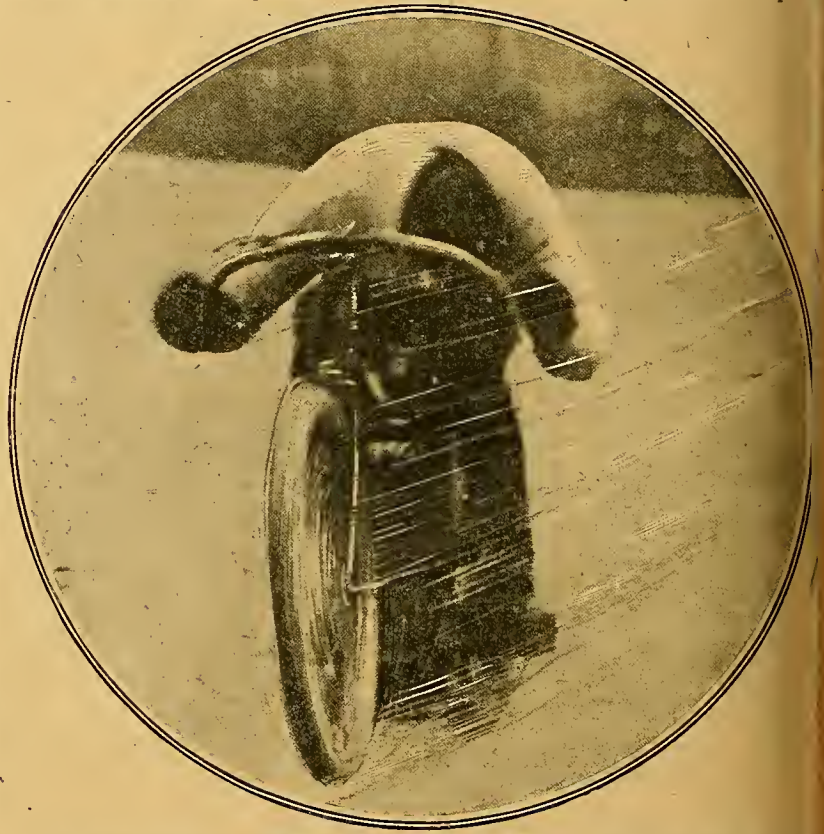
When riding my 5 h.p. twin Peugeot machine, if I cut down the gas one cylinder always stops firing before the other. I cannot account for this, as both inlets have the same strength spring, and they are fed by the Amac carburetter. I know the front cylinder has not quite the same compression as the back (and this is my experience with all Peugeot engines), but still I do not suppose this will account for what takes place. I might also mention that one cylinder appears to take rather more air than the other, but here again, when running along with the best mixture you can get, I do not see how this would cause the trouble. I want you to clearly understand that the one cylinder does not cut out until the gas has been very considerably cut down, but still I want both cylinders to go on firing to an equal point.—R. J. F.

The symptom described is by no means an uncommon one. If the engine is magneto fired, the maximum spark in one cylinder with a certain type of magneto occurs at a different point from that of the other cylinder. Consequently, although the two sparks occur at the right time, in the case of one a more feeble spark is given off than in the other. When the mixture is weakened by closing the throttle, the cylinder in which the weaker spark occurs misses fire. Also the fact that a slight difference in compression is to be found would tend to make the cylinder miss. The slightest variation in the amount of opening of the valves would also account for the symptom described.

Overheating and some Cures.

(1.) I have a twin-cylinder Kerry tricar which overheats very quickly, sometimes in about four miles. I try to rush hills quickly, but the engine suddenly slows down and stops. (2.) What takes place in the cylinder when overheating occurs? Does the charge fire before the time? (3.) Is the fault in carburetter? It is a Longuemare. I have the extra air inlet quite closed, and cannot open it the slightest or engine will stop. Should this be so? (4.) Would a new carburetter improve it much? If so, what make?—E. H.

(1.) The trouble seems to be clearly overheating, probably due to the engine being screened from cooling draughts by the forecar seat. (2.) The cylinder gets so hot that proper lubrication is almost impossible. If there is any carbon deposit, particles of carbon become incandescent and fire the charge prematurely, causing knocking and a sudden stop. (3 and 4.) It is possible that the fault is with the carburetter, but this we cannot say for certain. The best thing to do would be to have the cylinder and piston cleaned of carbon deposit, then grind in the valves, fit new valve springs, and see how the engine will run. If it will take the full amount of air when running fast after it has been running for about 100 miles, you will know that the carburetter is practically right. Failing this, you will be well advised to have handle-bar control fitted to your carburetter. You can possibly improve your present carburetter by experimenting with different size jets and cones until you get it so adjusted that it will only take full air when travelling at its highest speed. Do not overload or force the engine along, and lubricate freely.



AN IMPRESSION OF SPEED.

In order to offer the least possible resistance to the wind, record breakers duck their heads for short stretches, only dancing up occasionally to make sure that the coast is clear. The photograph depicts O. C. Godfrey during what is generally supposed to be the fastest ride ever accomplished on a single-cylinder motor cycle. His mount is a 3½ h.p. Rex.

A Twin-cylinder Bicycle with Sidecar.

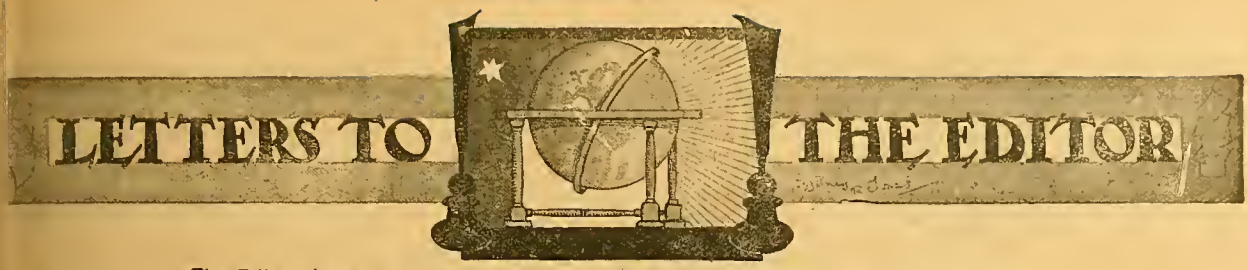
At present I have a 3½ two-speed free engine Bradbury, used nearly always with sidecar. I hope to run a two-speed 5 h.p. twin with sidecar. Are the costs much extra? About how many miles to the gallon should I get? Is there less vibration on a twin? Is it more difficult to start? Weight, 21 st. With my present 3½ h.p. several hills stop me unless I rush them. Now, with a 5 h.p. I ought to climb anything, but is it just as easy to drive and understand? Also (and this is important) can a twin be driven slowly in traffic?—F. R. L.

You should not find the cost very much more, say an extra 1s. per 100 miles at most. The consumption should average about sixty miles to the gallon. There is less vibration with a twin cylinder engine. Twin-cylinder machines are not difficult to start if the carburetter is properly adjusted. The machine should take you practically anywhere. You will find a good machine quite easy to drive and understand. Naturally, a twin requires slightly more attention, as most of the engine parts are duplicated as compared with a single cylinder. Of course, with the low gear it can be driven quite slowly in traffic.

READERS' REPLIES.

Chronic Misfiring.

Having experienced the same trouble as your correspondent "C.O.M." describes under "Chronic Misfiring" in the issue of February 14th, I recommend him to look to his earth connection, generally made between the switch block and the frame. The addition of a copper wire held under a nut on this block and secured to an adjacent nut on the frame, thus ensuring a sound earth connection, made all the difference in my case. He should trace the earth connection through all joints between the contact maker and switch.—E. B. WEDMORE.



The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, E.C., and should be accompanied by the writer's full name and address.

Causes of Overheating.

4593.]—Would "P. G. J." [letter 4575] be good enough to explain *how* a leaky induction pipe could cause overheating of the engine? The theory sounds feasible enough if referring to the condition of the *rider*, as far as concerns his efforts at starting. C. McC.

The A.C.U. Quarterly Trials.

4594.]—I think both the public and the trade must agree, after the showing up in your columns of the last Quarterly Trials, that Quarterly Trials are an absolute farce, an insult to sport, to the competitors, and to the trade, and I do hope that we shall not have a repetition of them in a few months' time.

The letters of disagreement in your columns are quite sufficient to ring the death-knell to the last of these useless competitions. W. WILLIAMSON.

Cubical Capacity and Horse-power.

4595.]—Mr. W. H. Wells certainly opens an interesting discussion regarding the so-called 5½ h.p. single-cylinder machine. Might I suggest that this class of machine should be rated at its b.h.p.—at the number of revolutions the engine would be making were it propelling the cycle at the legal limit? Gear ratio, say, 4½ to 1. A. BIRT.

4596.]—The leaderette in your valuable paper of the 14th inst., although on the right lines, does not go far enough, as horse-power is the rate of doing work. Why should the unit of time be left out? The true basis of comparison is cubical capacity per minute, therefore engine revolutions should always be quoted, or, better still, the ratio between speed of driving wheel rim in contact with road and the piston speed of the engine.

I should personally feel much indebted to your paper should makers eventually take the hint through its medium.

J. POLLOCK BROWN.

4597.]—I am much interested in the h.p. question. My engine has a cubical capacity of 340 c.c., is rated by makers at 2¾ h.p., and by the R.A.C. formula at 3.6.

Another well-known engine has capacity of 499 c.c., makers' rating 3½ h.p., R.A.C. formula 4.

Is this very confusing. Surely some simple rule can be agreed to, giving the non-technical rider a better idea of the comparative power of different engines. I suggest that the rating be on capacity—100 c.c. to equal 1 h.p. This, I believe, would work out very near the actual power developed at maximum speed, and much better for comparative purposes than either the R.A.C. formula or the makers' arbitrary statements. W 1590.

Change Speed Gears in Rhodesia.

4598.]—I have been a constant reader of your paper and also a motor cyclist for some years. During that time I have ridden several motor cycles, and for the past two years a 3 h.p. Vindec two-speed. I am an advocate of the two-speed gear for motor cycles, and the Vindec gear I use has given me entire satisfaction.

As most people have heard, the roads out here are abominable, and I have found it impossible to do much riding without a second gear to fall back on. With the exception of a very occasional adjustment of the distance rods, I have never had anything wrong with the machine, and the rough usage it has had goes to prove that it is absolutely reliable. H. M. JONES.

Salisbury, Rhodesia.

The Transmission Question.

4599.]—Mr. Vivian Olsson says in his letter 4571, February 14th, that to make the Whittle belt as comfortable as a rubber one a slipping or spring drive is required. Why not convert to chain drive, which is neater, lighter, and not so expensive or clumsy, and does not gather "mud" to throw over the machine and rider. All belts are doomed, for it is an old and crude way of transmitting power on motors. In the future it will be either chain or shaft transmission, which will become the more popular. I certainly favour the shaft on account of its being weather proof.

PONY.

Increase of Speed on Partially Raising the Exhaust Valve.

4600.]—I think the following practically proves the reason of increased speed on slightly raising the exhaust valve lever. I have a 5 h.p. twin and find (when travelling at any speed up to about 30 m.p.h.) on slightly raising the exhaust valve lever the speed increases; when the engine is running on the stand, if I slightly help the exhaust valves on their upward movement with my fingers, I get again increased speed. I removed these exhaust valve springs and fitted weaker ones, then when raising the exhaust valve lever the speed did not alter. I think, therefore, the increased speed is due to the strength of the exhaust valve springs, when strong (as they should be for high speeds) and you help the valves on their upward movement you take some of the work and pressure from the cams. I consider the more pressure on the cams the more it acts as a brake on the engine. I have also noticed that some twin engines fitted with side by side m.o.v. will increase their speed remarkably on slightly raising all four valves, thus helping the cams to overcome the tension of the valve springs.

B. G. DURKIN.

Metal for Exhaust Valves.

4601.]—In the issue of the 14th inst. you published a letter [4576] signed "C.M.B." This reader asks for a little enlightenment as to metals suitable for petrol motor valves. I beg to remind him that when castiron is used it is only for the head, as it would be a waste of time and material to make a complete valve of this material.

I have had considerable experience with the various air hardening steels, so can inform your correspondent "C.M.B." that it would be quite an easy matter to forge and turn a valve from the latest kind of high speed steel, as it can be very successfully annealed, but after the first time of running the motor it would, of course, harden again. After it had become hard the valve stem would break, not being able to stand the jar. The only fault of this steel is that when hard it will not stand the least springing motion.

I can see no advantage by making the head only of high speed steel, as this would be no advancement on the castiron head.

The subject is a most interesting one, and after carefully thinking the matter over I can only suggest—as an alternative to nickel steel—the use of Wolfram steel. This steel is unshrinkable, very tough and hard. I would recommend the welding Wolfram quality.

If a valve made from this material would keep a good face on the seating it would be ideal, as the length of the valve would not alter under the various temperatures to which an air-cooled petrol engine is subjected. Perhaps someone who has an engine which is particularly destructive to valves will try this steel as an experiment.

PERCY H. DUDLEY.

Awards in the Quarterly Trials.

[4602.]—Like many other competitors in the above trials, I must say I am dissatisfied with the awards, chiefly in relation to one rider's stop to another's. I had a stop, and though the road wheel never stopped I reported it, and expected to have marks deducted for it; but when I see others get full marks, although they stopped as much as I did, naturally I am dissatisfied.

Re Dashwood hill-climb, I had steel-studded tyres. I started from a standing start, and got up the hill successfully; yet others who failed get just as many marks.

I could go into a lot of detail, but do not want to take up your valuable space. I think the suggestion to reconsider the awards a good one. F. W. APPLEBEE.

Riding Costs.

[4603.]—I have ridden a 1907 pattern N.S.U. 1¼ h.p. lightweight over 13,000 miles, and have kept accurate records of my expenses over the whole of this distance:

	Cost per mile.
Petrol (126.3 miles per gallon) ...	0.114d.
Oil (3,000 miles per gallon)	0.015d.
Tyres (S.E. studded mostly)	0.082d.
Belts	0.013d.
Pulleys	0.017d.
Collan oil, plugs, etc.	0.011d.
Total running expenses ...	0.252d. per mile.

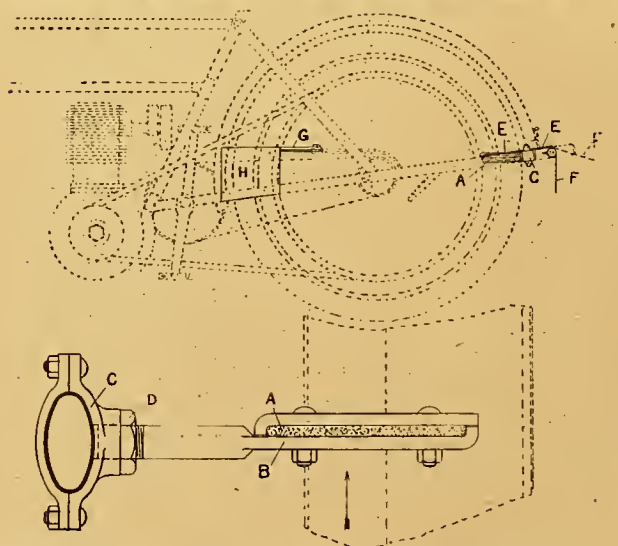
I have found the round twisted belt satisfactory if well dressed and on suitable pulleys, while my S.E. tyres have never punctured. The machine has been a model of reliability, the only serious defect being the breakage of a front fork. (The same machine now has spring forks.)

I must add, I suppose, the usual disclaimer. TEN STONE.

How to keep a Belt Dry and Clean.

[4604.]—In the issue of February 7th a correspondent has described an excellent method of keeping the belt clean. The placing of the brush upon the rear stays, as shown, is, however, open to the objection that the mud removed is unable to fall clear, but drops again upon the belt, rim, and frame.

The accompanying sketches show another position for the brush, which is free from this objection, and renders the



device less conspicuous. The brush A is held in a flat clamp B carried on the left leg of the stand. This leg being of oval section gives a firm support to the base C of the clamp. The width of the brush at the end of the bristles is two and a quarter inches, sufficient to clean the top of the belt and the outer circumference of the belt rim. When removing the belt one can slacken the lock-nut D and let the brush hang downwards.

The sketches show also: (1.) A horizontal shield E fitted across each of the bottom corners of the stand. (2.) A flap F pivoted on the crossbar of the stand swings out when machine is in motion, as shown by dotted lines, and is prevented from swinging forward at any time by a stop. (3.) A chain guard G, which forms an extension of the free-wheel cover, and is supported at the front by a vertical plate H passing down to and around the right chain stay.

These fittings are quite simple to make, and if done neatly they do not spoil the appearance of the machine, while they greatly reduce the labour of cleaning. CYRIL J. FEENY.

Finish for All-weather Machines.

[4605.]—"Pretty bits of plating may help to sell a machine to a novice, but I do not think a practical man wants them."

The above paragraph appeared in a letter received by my firm from a gentleman concerning the enamelling of all parts of a motor bicycle with the exception of handle-bars. From an economical point of view this would be a gain for the manufacturer, but not so for the purchaser. I ride twenty-seven miles daily backwards and forwards to business, and experience has taught me how careful one has to be to prevent enamel being scratched when removing mud from the frame be it wet or dry, and how quickly enamelled spokes get chipped and look shabby, and what an enamelled nut looks like, a spanner having once been applied to it. Plated parts with a little care last good for years.

For those who object to cleaning their machines after every ride, all that is necessary is to give the plated parts a thin coating of vaseline, allowing the mud to remain till a convenient time arrives to clean. Those, however, who like their machines cleaned frequently need not vaseline the plated parts, and should by any chance their machines be allowed to remain dirty for a day or two no damage will be done so long as they are kept in a perfectly dry place. When machines are sent us for repair or overhauling after two or three years of hard wear the enamelled parts are more or less, chipped and rusty. The frames and mud-guards often have large patches of enamel scraped or worn off, with rust eaten deep into the metal. In nearly all cases, however, the plated parts are free from rust.

Black enamel suffers most severely by wet or hard wear and coloured enamel more so, whereas plating, if kept dry will last for years. F. HULBERT.

Lightweights v. Heavyweights.

[4606.]—The letter by "Rus in Urbe" has amused me somewhat, but why does he not publish his name? Is he afraid of it? or does he not wish me to know that he really knows me and the work I do? Anyway, I prefer to answer a known rather than an unknown criticism, and so perhaps when he writes his apology to me in the next issue for his implying that I was lying in what I said, he will sign his own name in full.

Now in answer. He is criticising what he does not know or understand, and so is unfair, as most foolish people are under those conditions. My work does not consist in looking after one little tiny village in this part of Sussex. First of all, I am superintendent to a large orphanage, and my work consists mainly in that, hence I am called on to visit and ride to all parts of the country on business, and as fast as possible in all weathers, and at all times I use my motor cycle for the work. I do a very great amount of town riding, and know probably as much of traffic as most riders do. I am, in fact, constantly in a town near here on business, and if he saw me in Brighton, or Horsham, at work he would see how, why, and where a great many stops come in. Moreover, he criticises both my work and district, of which he evidently knows nothing. I have in my charge besides the orphanage here, a district some fifteen miles across, and very many of the villages have as many as ninety to a hundred houses scattered over two or three miles, and I have persons to see and visit in one village of 190 houses to the number of twenty-seven, and they are all scattered over a district of two miles. Again, if he knew the work I spoke of, he would be in a position to criticise fairly, and to see how it is necessary to make many stops in 117 yards. Has he any experience of boy scout work, has he ever laid trails for them to track, has he seen me on and off the motor doing this every hundred yards or so? (I use the machine for my work for the boys here.) Then again, does he know that I experiment when I have a chance with all sorts of measurements, and also all sorts of improvements for motor

The SERVICE "COLDWEATHER" JACKET.
An essential for Winter Riding. Value Exceptional.
Thoroughly Windproof.

Body and sleeves lined Tan Leather, fitted with windcuffs; 33in. long.
In Grey Yorkshire Frieze, 25/6 (approval deposit).
All sizes stocked. State chest measurement.

Chamois Leather Waistcoats from 11/6.
Black " " (Lined) 25/-

Special line Jaeger Woollen Caps .. 2/-
Jaeger Throat Protectors.. 2/-

Leather Gaiters from 8/6.

APPEARANCE COUNTS FOR MUCH.

SERVICE CAPS.
Made in Brown, Grey, and Green fashionable Tweeds.
Price 2/6. Best make and finish.

LONDON E.C.

In answering this advertisement it is desirable to mention "The Motor Cycle."

cycles, and that the information is got for the purposes of the engineering shop that we have here for the boys, and where the boys are taught, so that sometimes we are out on the road, stopping and starting at all sorts of distances? Now if "Rus in Urbe" would use discretion before he rushes into criticism of the work I do, and if he knew the country round here, and knew that there are more than one or two houses every two miles, then he might have some reason to speak; moreover, he says I speak from country experience only. Has he verified that, because again he is wrong. I also ride and use my machine in town; in fact, I am just back from Southampton, where I have been working for two days, and using my machine the best part of the day, dodging traffic, etc., and I still say I prefer what I have, a good reliable heavyweight (or medium weight as the Triumph is), after having had a lightweight or two, and having ridden several for the purpose of experiment, just because in my opinion for all-round work the heavyweight gives me less trouble, and is more reliable than any lightweight I have tried, bar (as I said) the P. and M. No, "Rus in Urbe," you criticise unfairly, and I ask for an apology for saying or implying that I was lying, because you know nothing of myself or my work, and you cannot gather it either from maps or directories. You like the lightweight best. I prefer the heavyweight for my work, but it does not say, as I said in my letter, that either of them is the best in all things. (Rev.) R. MEASURES.

West Grinstead.

Standardisation of Rims and Tyres.

[4607.]—We hear a great deal just at present about the great improvements that have been and are being made in motor cycles. I think there is one point in which there is room for much improvement, and that is in the standardisation of rims. This week through a bad burst in my back tyre I had to order a new cover from a well-known firm. On arrival it was, though stamped 26 × 2¼, found to be a great deal too large for the rim. Result, a delay of two or three days before I can obtain one that will fit. The delay does not matter a great deal at this time of the year, but would be most vexing if it had occurred in Easter week, or any time for that matter during the spring or summer (if we have any). EX-LIGHTWEIGHT.

[We have repeatedly referred in leading and other articles to the question of standardisation of rims and tyres. We also published on May 22nd, 1907, information obtained from tyre manufacturers as to the different sizes of tyres of their own make, which are interchangeable on one rim. The number of makers has increased since that date, but we do not think we are any nearer to a solution of the difficulty. The best course for readers to adopt when ordering replacements is to specify the same make and size again, except when they wish to change from 2in. to 2¼in. of the same make, when no change of rim is required with the following: Clincher, Continental, and Dunlop. Palmer 2¼ and 2½ tyres fit the 2½ rim, and 2¼ tyres will fit the 2in. if clearly specified when ordering. We shall be glad to publish the names of any other tyres which are interchangeable.—ED.]

Variably Geared Lightweights.

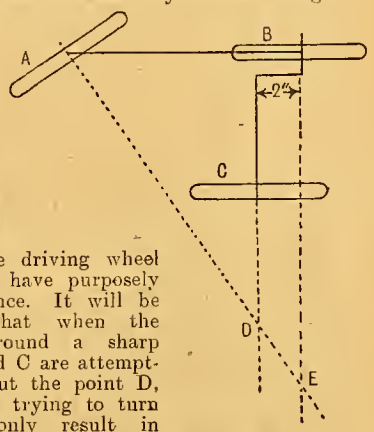
[4608.]—With reference to your leaderette in the issue f February 14th, "Variably Geared Lightweights," with he pith of which we fully agree, we wish to call your, and, hrough your courtesy, also your readers', attention to the act that we can now supply, in addition to our ordinary o. 1 model Nala gear for twin machines and passenger ork, the new No. 0 model, which is especially designed for ghtweight machines and single work. This new model hub ear is a copy of its larger brother, but very much lighter hroughout and weighs only about 17 lbs. Being a hub-ear and built into the back wheel, it adds no weight whatver to the frame and has proved to be suitable and efficient n any of the lightweight machines at present on the market, o matter how light the frame and small the h.p. We do ot care further to decrease the substance (and weight) of is hub, as we consider it impossible to do so without a crifice in reliability. Indeed, the next step towards lightess would be a type of pedal cycle two or three-speed gear s at present on the market with which we have experiented on a lightweight machine, and, even under least exting conditions, our tests usually ended up in obtaining a "permanent free engine position." It is obviously necessary, in order to obtain a satisfactory and lasting two-speed gear on a lightweight, to add a certain amount of weight, and we maintain that an additional weight of about 17 lbs. is not excessive in view of the distinct advantages gained in several other directions. Speed need not be sacrificed, as it will be possible, with a second speed and free engine, to gear the machine higher for top speed.

We are prepared to place a new model "lightweight" hub at the disposal of any manufacturer of lightweight motor cycles for experimental purposes. Incidentally, we may also remark that we hope, before many months are past, to be manufacturing the Nala gear throughout in this country. THE NALA HUB CO.

A. HOTOPF.

Steering of Sidecars.

[4609.]—In the issue of February 14th I see that my friend Mr. Herbert Porter tells how he has overcome his difficulty in steering a sidecar combination. Since he explained the matter to me the other day I have thought it over, and, as the real fault is obviously one of design, and deserves the serious attention of makers, I venture to give a short explanation.



It appears that Mr. Porter's machine is "cranked" in the frame, so that the side wheel axis is two inches in front of the driving wheel axis. In my sketch I have purposely exaggerated this distance. It will be seen at a glance that when the machine is turned round a sharp corner the wheels A and C are attempting to turn round about the point D, whilst A and B are trying to turn about E. This can only result in straining the framework, and it is liable to set up slipping or grinding at the road surface, and perhaps wobbling of one or more of the wheels.

Since the principles underlying the Ackermann type of steering four-wheeled cars are so well known, it is surprising that they should be overlooked in designing the far less stable three-wheeled combination. To apply the principle here is simply to ensure all three axes of the wheels meeting at a single point, and it is clear that this can only be done by keeping the axis of B in line with that of C.

J. H. LESTER.

SUMMARY OF CORRESPONDENCE.

"EJ 61" strongly eulogises the Star detachable belt fasteners with extension hook, made by S. T. Robson, 59 Holmoor Road, Birmingham, and says: "They never pull through, owing to the spiked fastening; are very easy to fit, owing to the peculiar worm on the screw; and the one extension hook with its three holes does away with the necessity for short bits of belt. One I have had in use over 2,000 miles appears good for twice that distance still."

EXPERIENCES WANTED

"R. B." (West Ealing) wishes to know if any reader can recommend a two-speed gear for belt transmission to be fitted in front of crank case and to run at half engine speed, rotation of engine not to be reversed.

"Willoughby" (Ledbury) would like readers' experiences with Palmer Cord, Shamrock-Excelsior (rubber-studded), and Kempshall non-skids on the driving wheels of twin-cylinder motor cycles with sidecars.

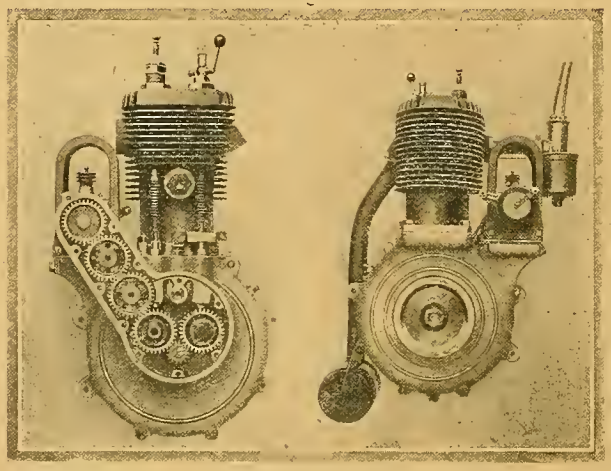
"E. G." (Johannesburg) would like to hear from any reader who has visited Vladivostock in recent times, who could inform him if it would be any use taking a motor or pedal cycle to that town. He expects to be a resident there for about two years.

"H. S." (Liverpool) would like readers' experiences with the L.M.C. Auto Variable pulley and free engine on a 3½ h.p single-cylinder motor bicycle with sidecar.

A NEW PATTERN 3½ h.p. PREMIER.

NOTWITHSTANDING the success attained by the 3½ h.p. single-cylinder Premier as exhibited at the Stanley Show, the makers have not allowed grass to grow under their feet, and, in addition to redesigning the machine throughout, have adopted a new feature in their engine which promises to solve most of the common difficulties with present day engines, such as knocking, overheating, and exhaust valve troubles. This feature is in connection with an auxiliary exhaust release, and, whilst being new to touring motor cycles, is a common feature of engines on racing motor cycles and aeroplanes. The manner of arranging an additional exit for the burnt gases in the case of most racing and aeroplane engines is crude to a degree, holes merely being drilled in the cylinder walls, and the gases allowed to exhaust into the open air.

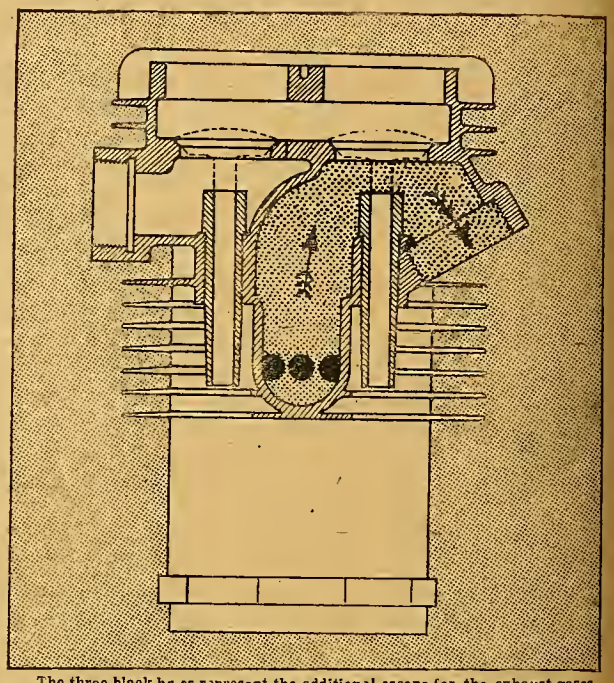
In the case of the Premier engine, which is shown in section in the accompanying line drawing, much



Left and right hand views of the engine, showing the gear drive for the magneto, and aluminium platform for the latter at the rear of the cylinder.

care and ingenuity have obviously been displayed in the design, as the gases which emerge when the piston reaches the bottom of its stroke are conducted upwards along a passage formed in the cylinder to the exhaust pipe and silencer, intermingling with the gases issuing *viâ* the exhaust valve. The result of this design is a neat looking engine, the additional exhaust outlet being quite unnoticeable except for the inspection cover seen in the left of the two half-tone illustrations of the engine.

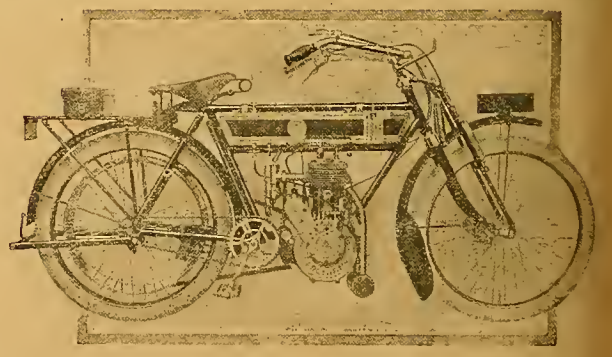
For the benefit of novices, we may explain that the main object of auxiliary port holes is to get rid of the hot gases more quickly, and so enable the engine to run at a cooler temperature, which of course means an increase of power and less likelihood of knocking and pitting of the exhaust valve seat. Just before the piston reaches the lowest point of its travel, the three holes (shown black in the illustration) are uncovered and the burnt gas allowed to escape under pressure, the scavenging action of the piston on the next upward stroke completing the work of cleansing the cylinder of any burnt gas remaining, the exhaust valve being open during this stroke. It will be obvious that the exhaust valve is in this manner relieved of much of the burning action usual with engines of the orthodox type. Moreover, by completely scavenging the cylinder, a bigger charge is induced on the next down stroke. It is a matter of small wonderment



The three black holes represent the additional escape for the exhaust gases when the piston reaches the bottom of the firing stroke. The gases are conducted along an enlarged chamber and emerge, as shown by the arrows, *via* the exhaust pipe and silencer.

that some such idea has not already become general, as there is no extra complication in the slightest, yet the benefits accruing are agreed to be considerable.

The bore and stroke of the new engine are 85 × 88 mm., representing a cubical capacity of 499.4 c.c. The valve timing gear has been rendered extremely simple. At the back of the half-time wheels, cams



The 1910½ pattern Premier with auxiliary exhaust release holes in the cylinder.

are formed operating the tappets by means of large steel balls carried in their ends. Thus no bell cranks are used. The radiators on the cylinder casting are parallel and vertical on the combustion head to assist in cooling.

The magneto on the new model is mounted at the

A New Pattern 3½ h.p. Premier.—

rear of the cylinder on a platform cast integral with the crank case, and is gear driven. This has necessitated the B. and B. carburetter being moved further back, and we are told that the longer induction pipe has had a beneficial effect on the running of the engine, ascribed to a more perfect mixture. The suspension of the engine has also been improved, and by rendering the power unit more compact, it has been found possible to shorten the wheelbase of the bicycle. Other lesser important innovations are in connection with the spring fork, and a more convenient position for the lubricating pump, the latter having been moved from near the saddle to an inclined position at the forward end of the tank. Every part of the new Premier has been designed with an eye to accessibility, and the centre of gravity has been kept low.

We expect a good deal of this new model, and the makers are to be congratulated upon their enterprise and originality.

CHECKING IN RELIABILITY TRIALS.

A REPLY TO "D. E. A."

By FELIX SCRIVEN.

WHEN the system of checking which I described in *The Motor Cycle* of February 14th was under discussion by the Bradford M.C.C. Competitions Committee, the point which "D. E. A." alludes to was brought up in argument against the proposed system.

In practice, however, we have not found the production of the watch to cause any undue delay. As stated in my description of the system, the sealed watch case can be fixed to the handle-bars of the machine or strapped to the arm or wrist of the rider.

Out or Home Book A

CHECK..... miles to.....

..... miles from.....

Competitor's No.....

Time.....

Checker's Sig.....

A leaf from the Bradford M.C.C. Checking Book.

Personally, I adopt the former idea, as the watch is then always under the eyes of the rider. A checker is generally visible at least thirty or forty yards before reaching the spot at which he is taking the check, and I hold that any machine fit to be on the road should be easily capable of being stopped in that distance by the brakes when travelling at 20 m.p.h.

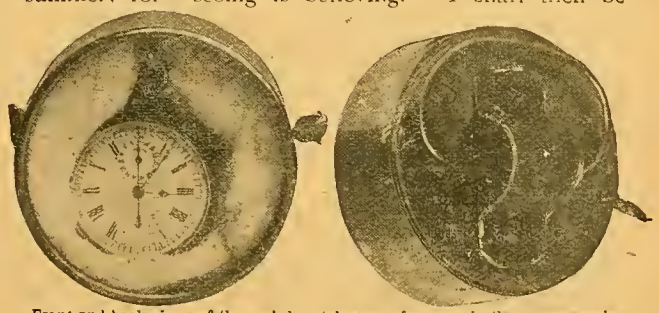
If the competitor attaches the watch case to his arm or the handle-bar, he does not even need to move from the saddle until the time has been read from his sealed watch by the checker, for he has only to put his feet to the ground as soon as the machine is at a standstill.

Now I contend that a good reliability trials rider should "expect" a surprise check at *every* milestone *en route*, and he should be on the look-out for a checker as soon as he knows that he is nearing the "danger zone" of a mile-post, and also that, to pull up with promptitude and to have his watch case sufficiently accessible to be able to produce the same with alacrity, is one of the things a competitor must learn if he is to be successful.

Furthermore, should a competitor really find that in producing his watch he consistently loses a few seconds by delay, he can obviously overcome this difficulty by always riding just a few seconds ahead of his scheduled time.

From personal experience, both as a checker and competitor, I have every confidence in recommending the system, and I think it is safe to say that all members of the Bradford M.C.C. who have taken part in these competitions will confirm my statement.

I have not the pleasure of recognising the identity of "D. E. A.," but should the distance not be too great for him, I should be only too delighted to tender him an invitation to attend one of our trials during the summer, for "seeing is believing." I shall then be

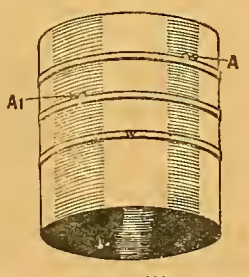


Front and back views of the sealed watch case referred to in the accompanying article.

pleased more fully to explain any details, so that "D. E. A.'s" club may some day enjoy the freedom from "checking grumbles" which the Bradford Motor Cycle Club now enjoys.

A NEW DESIGN OF PISTON RING.

VARIOUS methods have been adopted for preventing the slots of piston rings from getting into line, the latest to be brought to our notice being the invention of Mr. R. Webb, 30, Glyn Road, Homerton, N.E. Mr. Webb manufactures piston rings with a small semi-circular boss on one edge which fits a corresponding recess in the piston groove. The result is that the rings cannot move circumferentially, but are said to be otherwise perfectly free. Mr. Webb has tried the rings on a motor bicycle, and assures us that the results are as good as, if not better than, he anticipated. The device is provisionally protected. The appended sketch clearly illustrates the nature of the invention, the bosses and recesses A and A_1 preventing the rings from moving, and, in consequence, the slots from getting into line.



COMPRESSION.

By ERIC W. WALFORD.

EVERY keen motor cyclist knows the importance of having good compression, but very few realise why compression is of such importance, as it would appear that the compression stroke must absorb a considerable amount of power, and it is difficult to see how any advantage is gained. The operation of the steam engine is extremely easy to follow. Steam enters the cylinder when the piston is at the top of its stroke, and forces it down to the bottom of the stroke, whilst on the return stroke the piston forces the steam out. In the petrol engine three of the four strokes of the Otto cycle are easy to comprehend, but the fourth presents considerable difficulty to the lay mind.

In the olden days of muzzle loading rifles it will be remembered that it was customary to ram down the powder hard before inserting the bullet. Here is an analogy. The charge was compressed before it was fired, but the reasons in both cases were not exactly the same. The impact from gunpowder is, however, greater when the powder is compressed than when in its normal state, as can be easily verified.

Non-compression Engines.

Early gas engines—which, of course, were the forerunners of the petrol engine—worked on a non-compression cycle and very closely followed the steam engine in operation. As the piston started on the down stroke it sucked in gas for about half a stroke, the inlet valve was then shut and the gas immediately fired, an impulse being thus obtained which took effect for the remainder of the stroke; on the return stroke the burnt gas was exhausted. An indicator diagram somewhat resembling fig. 1 was obtained. The line A D represents the piston's travel. From A to C suction took place, and the pressure in the cylinder fell below that of the atmosphere, the line A D being taken to represent atmospheric pressure. At C the charge drawn in was fired and the pressure went up rapidly to B, gradually falling as the piston travelled outwards and expansion took place. Engines working on this system, invented by Lenoir, were very inefficient in comparison with present day engines, and also gave very little power for their size and weight. The consumption worked out at 80 cubic feet per indicated horse-power per hour, and a 3 h.p. engine weighed more than three complete motor bicycles nowadays. Present day engines consume about 20 cubic feet of gas for the same work.

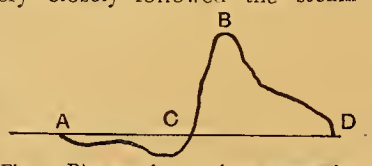


Fig. 1.—Diagram of curve of non-compression engine.

Loss of Heat to Cylinder Walls.

Now for the reasons why this should be so. It will immediately be noticed that, in comparison with the present day engine, suction only took place for half the stroke, and therefore only half the volume of gas was taken into the cylinder as compared with the modern engine. Again, at the moment of ignition, half the surface of the cylinder walls was exposed. In order to obtain efficient working it is essential that a minimum surface be exposed at the moment of ignition, so that the heat generated be not lost to the cylinder walls and radiators, or water jackets in the case of a water-cooled engine. The cylinder, radiators, and jackets are essential for other purposes, but they may be looked upon as necessary evils in the matter of efficiency. In the Lenoir or non-compression engine at the moment of ignition a great deal of heat was lost to the water jacket, so that the pressure obtained was nothing like as high as would be the case if a smaller surface were exposed.

The Proportions of Combustible Mixture.

By compressing the gas a very much weaker mixture can be used. In the older Lenoir engines the best results were obtained with a combustible mixture of a proportion of sixteen to eighteen parts of gas to one hundred of air, whilst in the modern engine this ratio is seven to ten parts of gas to one hundred parts of air. The particles when compressed are closer together, and less time is taken to effect combustion, and more power is thus got out of the compression engine. The same applies to the combustible mixture in modern engines. That is to say, a high compression engine would be more economical in running than a similar engine with a lower compression, provided the conditions were not altered.

Again, in an engine with a high compression there is less space that is not swept by the piston, and consequently less exhaust gas is left in the cylinder to dilute the next charge.

Indicator Diagrams Compared.

In fig. 2 are given two indicator diagrams taken from a gas engine in which the compression had been raised. As before A D indicates the piston stroke as usual, and the curve shows the rise and fall of pressure on the

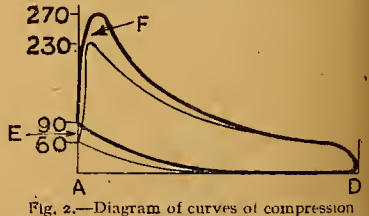

Fig. 2.—Diagram of curves of compression engine

Compression.—

compression and firing strokes. The line D E shows the rise of pressure as the piston moves back to compress the charge. After ignition the pressure rises to F and falls gradually to D. It will be noticed that there are two diagrams, one shown as a thin and the other as a thick line. Dealing first with the thin line diagram, the compression was brought up to 60 lbs. to the square inch. On ignition the pressure rose to 230 lbs., and fell gradually till just before D was reached, when the exhaust valve opened. When the compression was raised to 90 lbs. the maximum pressure went up to 270 lbs.

It is not possible to give an exactly similar diagram taken from a modern petrol engine, owing to its very high speed, but the one reproduced serves to show roughly the effect of raising the compression, and as the area contained by the diagram is representative of the power the engine gives, it will be noticed by rough measurement that the power developed with the thick line diagram is very much greater than with the thin line diagram.

Disadvantages of Too High Compression.

During the last few years the compression in motor cycle engines, especially for competition purposes, has been raised considerably above what was the case a few years ago. This has resulted in very much higher efficiency—that is to say, the power obtained from a given engine and also the fuel consumption have been improved. There are, however, certain causes which limit the compression pressure. These are chiefly (1) preignition, especially at low engine speeds, (2) the necessity for a large flywheel, (3) difficulty in starting and running slowly, and (4) great stress or strain on the parts of the engine.

Generally speaking, the effect of raising the compression in an engine of given dimensions is to increase the power and the speed obtainable from the engine, but the gear ratio employed between engine and road wheel must be lower. A high compression engine will run very much faster than the same engine with a low compression, and will give more power, but at a higher speed. It is useless, therefore, to expect such engines to develop the same power at low speeds which they do with the lower compression. This has been expected with such engines, with the result that they have been said to "overheat."

I have obtained exactly the same effect with a water-cooled engine on a car, this engine having very high compression. It was found that the engine would give very high power at high engine speeds, but directly it slowed down it knocked and gave all the symptoms of "overheating" experienced with racing machines.

Different Methods of Raising Compression.

From the above remarks I do not wish it to be taken that the compression should be high, and I cannot recommend anybody with a standard engine to raise the compression except by a very small amount, and then only if it has been proved to be too low. The compression of an existing engine can be best raised by using deep caps over the valves, which is the simplest and safest method. Other methods are:

(1) To bolt a plate on the top of the piston, which is bad practice, as it is difficult to secure, and upsets the balance of the engine. It would also be likely to cause preignition on account of irregularities.

(2) To lengthen the connecting rod. This again upsets the engine balance slightly, and if the connecting rod is much longer than the old one it may foul the cylinder whilst at half-stroke.

(3) To turn off a portion of the bottom of the cylinder, and so lower it in relation to the piston. As the cylinder is bolted to the crank case by a flange or web at its lower end, it is obvious that this method will weaken the cylinder at this most important point.

(4) To fit a longer piston. This may bring the piston above the cylinder port, and it may upset the balance.

All Leakages must be Avoided.

It is far better to obtain *good* compression than a high compression in the engine; good compression means absence of all leakage. If there is any leakage

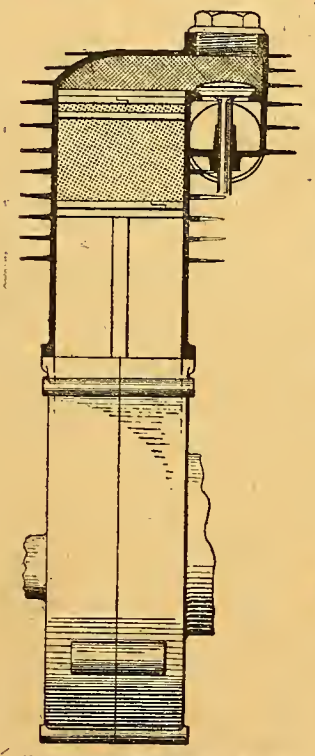

Fig. 3.—Showing piston at the top of its stroke.

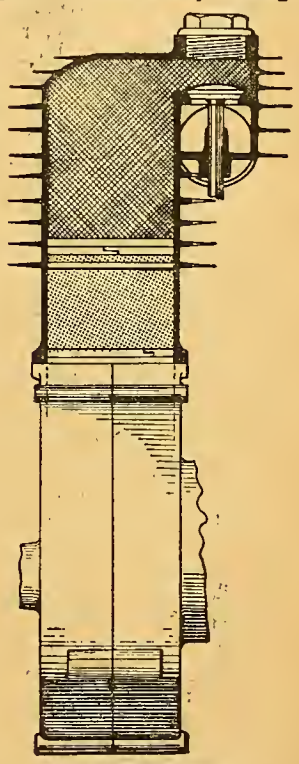

Fig. 4.—Showing piston at the bottom of its stroke.

the engine will draw in air or waste gas through this leakage on the suction stroke, slightly reducing the filling of the engine with fresh gas. On the compression stroke part of the gas in the cylinder will be forced through the leakage, and on the firing stroke more of the gas under pressure will leak through, and the pressure fall. It is therefore not only necessary on the compression stroke to have absolute gas tightness, but also on the other strokes.

The altitude and barometer reading both have their bearing on the compression pressure and also on the output of the engine, and atmospheric pressure may effect a relatively large variation in power. In the British Isles, where roads are not at a very high elevation, as in some other countries, a range of compression between 60 and 90 lbs. per square inch in the same engine can be obtained, so that natural causes have a considerable bearing on the power of the engine.

Compression.—

It is extremely difficult to measure actually what will be the compression in any given engine, as it is affected by the temperature, and the amount of this is an unknown quantity. There are formulæ for this purpose, but they will not interest the majority of motor cyclists. Generally speaking, the temperature is ignored, and the compression pressure considered at normal temperature. For this purpose one must know the total volume inside the cylinder and the valve ports, both when the piston is at the top and the bottom of its strokes. Assume, for the sake of argument, that when the piston is at the top (fig. 3) the volume shown shaded is five cubic inches, and when the piston is at the bottom of the stroke, as shown in fig. 4, twenty-five cubic inches. We can then ascertain the theoretical compression, ignoring temperature. The pressure of the gas in the shaded part of fig. 4 is at atmospheric pressure—that is to say, roughly, 15 lbs. per square inch. If now the gas be compressed into a space of half its previous dimensions the gas is raised to twice its original pressure—that is to say, 30 lbs. per square inch. If compressed into a volume one-third of its original dimensions the pressure is raised three times —that is to say, 45 lbs. per square inch. From this we obtain the rule—

$$\text{Compression pressure} = 15 \times \frac{\text{Shaded volume in fig. 4} = 25}{\text{Shaded volume in fig. 3} = 5}$$

Working out our figures on the lines of the above rule, it will be seen that the compression in the theoretical case being dealt with is 75 lbs. per square inch. It is therefore possible for anybody to ascertain in this manner what the compression of his engine is, provided he can find out the volumes shown shaded in figs. 3 and 4. It is possible to calculate these roughly for experiment, but the best method is to set the piston as shown in fig. 3 and see that both valves are tightly closed. Then pour in some innocuous liquid, such as very thin oil, which will not adhere to the cylinder, so as to fill up the whole space and not leave any air bubbles. This liquid should be accurately measured in pouring in. As the volume is ultimately required in cubic inches, the amount of liquid poured in must be transferred to cubic inches. (It may be useful to mention that one pint of water equals 34.6 cubic inches.) Having ascertained what fraction of a pint fills the shaded space, the cubic inch capacity can be ascertained by taking the same proportion of 34.6.

Having effected this very carefully, and seen that no bubbles exist, the engine should be turned round till the piston is at the very bottom of the stroke. Further liquid must now be added to bring the level the same as before, and this additional liquid must be measured and the measurement added to that previously obtained. You now get two values—one that of the gas drawn in (fig. 4) and the other of the gas compressed (fig. 3).

THE FUTURE OF THE END-TO-END RECORD.

WHAT is going to be done about the End-to-end record? The existing figures imply a nett average speed of close upon thirty miles an hour. Allowing for even brief stoppages, any successful attempt upon the record probably necessitates a gross average of over thirty miles an hour. Much of the route compels speed to be often reduced for a mile or two at a time to less than legal limit. One or two long stretches convert legal limit into a temporary maximum for considerable distances, *e.g.*, across the factory districts of Lancashire, and during the portion ridden in darkness. Ultra high speeds over much of the road are inevitable. Any danger, whether to the rider or the public, arising from the above considerations is greatly enhanced by the fact that the rider's vitality is almost always sub-normal for a period at any rate of the ride.

Will Higher Powered Machines be Used?

Consequently, if the attempts are recommenced this next summer, two very unpleasant possibilities are on the *tapis*. One is that some very decent young sportsman—an undergraduate or an example of our best type of amateur clubman or trade rider—may be either seriously injured or killed; the other is that some accident may occur to a third party. This will bring great discredit on the sport, and may have exceedingly nasty consequences for any firm of manufacturers concerned in organising what is plainly an illegal advertisement. The possibilities are enhanced when we remember that few modern aspirants depend upon personal knowledge of the route. The average aspirant depends over each section upon a leader, mounted on a fast machine, who pilots him over the tricky portions of the route, while from three to six followers hang on his heels, prepared to take the lead in the event of any mishap to the original pilot. Thus we have all the ingredients essential to a very pretty smash. If a catastrophe occurs, as is easily possible, the consequences will be disastrous in the worst sense to the immediate participants, while they will further reflect heavily on the trade and the pastime.

Further Attempts Anticipated.

It may be said that the record figures are already reduced to vanishing point, and that further attempts are improbable. This contention is contradicted by facts. Unsuccessful attempts have already been made upon the existing record; and these attempts have not been merely the forlorn hope of amateur sportsmen, but the organised advertising campaigns of commercial bodies. I personally know of several riders who are itching to have a go at the record, and amongst them I could name men who are seriously disqualified both by physique and mentality. Numerous attempts may be anticipated, and some of them will be made on faster machines of higher power than any which have so far aspired to honours over the route. I have already stated the dangers of giving those interested a free hand, as they appeal to me personally; and I am strongly of opinion that further attempts ought to be stopped with a strong hand. If authorities differ, it is none the less possible to control further attempts. If the Auto Cycle Union and its affiliated clubs announce their intention to place a life suspension upon any individuals, firms, or clubs concerned, the procession will automatically cease; and if a few stray riders should ignore the ban, they are not likely to get very far without backing from the trade.

B. H. DAVIES.

Oxford M.C.C.

Nine new members have recently been elected, making a total membership of fifty-eight.

Leeds M.C.C.

The dinner and distribution of prizes at headquarters took place on Friday last. The new president (Mr. Rowland Winn) presided.

Worcestershire M.C.C.

The A.G.M. will be held at headquarters, Golden Cross Hotel, Bromsgrove, on Saturday, March 12th, at 6.30 p.m. All motor cyclists in the district who are not at present members of the club will be cordially welcomed at this meeting.

Dublin and District M.C.C.

With the object of furthering the pastime of motor cycling by promoting competitions and sociability amongst motor cyclists, the committee of the above club requests the support and co-operation of Dublin motor cyclists. The annual subscription is 7s. 6d., and the honorary secretary will be pleased to hear from prospective members at any time. The printed programme, with full particulars of all events, will be ready early in March.

Liverpool M.C.

The committee has arranged the following programme for March at headquarters: Tuesday, 1st, semi-final and final matches, billiard handicap; Friday, 11th, Dr. Larkin's lantern lecture entitled "Places of interest from River Mersey to River Wye"; Thursday, 17th, return billiard match with Manchester Motor Club; Friday, 18th, committee meeting, instead of 25th; 25th to 28th, headquarters for Easter, Beddgelert, North Wales, inter-club meet with Manchester Motor Club.

Harrogate and District M.C.C.

A very successful motor cycle gymkhana was held on the Dragon Road Roller Skating Rink on Saturday evening, February 19th. The events, with winners, are as follows: Slow race, Mr. W. Grange riding a lightweight N.S.U. Musical chairs, Mr. F. Bagshaw (T.T. model Rex). Obstacle race, Mr. H. Fortune (3½ h.p. Triumph). Foot and wheel race, Mr. Grange, who also obtained the special prize for the best performance during the evening. The machines represented were N.S.U., Moto Rêve, Rex, Scott, and Triumph.

Motor Cycle Club for Leicester.

The first meeting, which was announced in these columns last week, was well attended, and the outcome was the formation of the Leicester and District Motor Cycle Club. Dr. Moss-Blundell presided over a good attendance. After the approval of rules, and competitions and social outings had been discussed, the officers were elected as follows: Chairman, Dr. Moss-Blundell; treasurer, Mr. E. G. Fowler; committee, Messrs. W. T. Glover, F. J. Hill, H. J. Marsden, D. M. Paterson, H. E. Smith, and G. H. Upton; and Mr. F. C. Poecher, of 20, Granby Street, as secretary. The opening run was fixed for Sunday next, March 6th, at 2.30, when the club members will meet at the tramway terminus, Oadby, and journey to Market Harborough. Great stress was laid by the meeting upon the considerate driving of members. New members will be gladly enrolled on applying to the hon. sec. at the above address.

Burnley Victoria C. and M.C.

The newly-formed motor section of the Victoria Cycle and Motor Club are holding another meeting in the Central Commercial Hotel, St. James's Row, Burnley, to-morrow (Tuesday), at 7.30 p.m. Will any local motor cyclists who would like to join the club kindly attend this meeting?

British Motor Cycle Racing Club.

The annual subscription to the B.M.C.R.C. is two guineas, and not as stated in last week's *Motor Cycle*. To members of the Brooklands Automobile Racing Club, however, the subscription is only one guinea. The hon. secretary of the club is Mr. T. W. Loughborough, Ashleigh House, Erith, Kent.

Western District M.C.

On March 6th a paperchase has been arranged from headquarters, meeting at 10 a.m., and finishing at the Bull Hotel, Gerrard's Cross The other runs for the month of March are: 13th, Virginia Water; 20th, Barnet; 27th, Amersham.

The club is progressing favourably, several new members having been enrolled.

Manchester M.C.

Mr. A. E. Bennett gave a lantern lecture on the "Bosch Magneto" to the members of the above club, numbering some sixty or seventy, at the club's headquarters, the Albion Hotel, Piccadilly, Manchester, on the 15th inst.

The inter-club billiard match with the Liverpool Motor Club resulted in a win for the Manchester team all through. A return match is to be played at Liverpool on March 17th.

Bishop Auckland, Darlington, and District M.C.

On the 3rd March a lecture, "The Law and its Relation to Motorists," will be delivered by Mr. H. Dewhurst at the Wear Valley Hotel, Bishop Auckland, 8 p.m. On the 16th, hot pot supper and smoking concert, at 7 p.m.; and on the 22nd, lecture "A Tour on the Continent," by Mr. T. W. Craig, illustrated, at 8 p.m.—both at the Wear Valley Hotel.

Birmingham M.C.C.

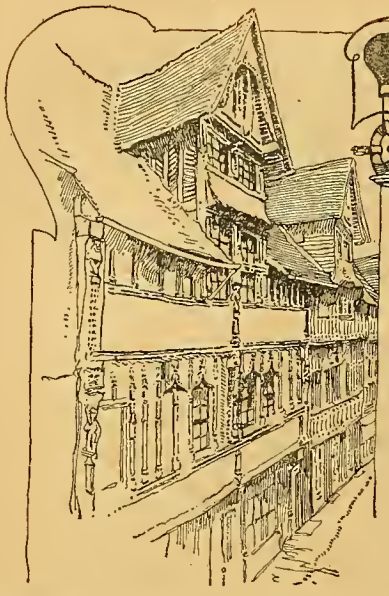
Five new members were recently elected. Readers wishing to join the club are advised to write Mr. R. Vernon C. Brook, the hon. secretary, Oakdene, Cambridge Road, King's Heath, Birmingham, at once for particulars of membership, advantages, etc., so that they may take full advantage of the 1910 competitions and fixtures. The club has now a membership of over 100, and it is hoped to increase this to 150 before the end of 1910.

Surrey M.C.C.

This club held a full committee meeting at the Angel Hotel, Guildford, on the 22nd inst., under the able chairmanship of Mr. R. Bryett. Runs, trials, and competitions proposed to be held during the ensuing season were discussed. A reliability and time trial is one of the chief events, to be held on May 25th to Lyme Regis and back, a distance of 121 miles either way. A petrol consumption trial will be held on June 22nd, and run in three classes—singles, twins, and lightweights. It is also proposed to hold a speed-judging competition on April 6th and a hill-climbing competition on September 7th.

The first of a series of social evenings will be held at the famous Surrey hostelry, the Anchor Hotel, Ripley, on March 9th next, at 8 p.m.

FURTHER NEWS FROM THE CLUBS APPEARS IN THE SUPPLEMENT.



A T.T. MODEL as a TOURING MOUNT.

IN the absence of close acquaintance with the subject, one might reasonably assume that a motor bicycle conforming with the regulations of a *Tourist* Trophy Race should be a perfectly satisfactory article for touring in the commonly accepted sense of the word. That all the machines built to compete in these events could be made to serve the dual purpose of racing and every day use cannot certainly be maintained for a moment, but having been lucky enough to hit on this admirable combination, and in view of the idea, which seems to prevail, that every maker's T.T. model is a racer and nothing more, I think a short account of my experiences with this type of machine may perhaps serve to dispel any misconceptions regarding them.

About seventeen months ago I had satisfactorily disposed of my old and well tried 3 h.p. motor cycle, and the problem of replacing it had next to be solved. The T.T. race was imminent, and being desirous of competing I reflected that it was highly improbable that the maker's standard touring machine, with its greater weight and unhandiness, would offer sufficient chance of success to justify the payment of a somewhat high entrance fee, excellent though such a machine might be for non-racing purposes. On the other hand I could not under any circumstances afford one of each model, and the prospect of purchasing a mount suitable only for use during ten days in the year could not be entertained.

A Disagreeable Voyage.

However, after some deliberation, the upshot of the matter was that the T.T. Triumph had it. The machine was taken straight from the works; and in its company I set out for Douglas, I.O.M. The crossing was disagreeable, and, as salt water spells ruination to the ordinary waterproof cape, staying on deck in any but a sheltered spot meant a thorough soaking. Still, having inadvertently reduced myself to an extremely critical condition a short while after leaving Liverpool —by sitting over a book with my back to a hot funnel in a surrounding atmosphere of greasy cooking—it became clear that if the situation were to be saved at all, there was nothing for it but to take up a position in the teeth of the wind and remain there, defying rain and spray, for the rest of the trip. Actual disaster did not, happily, overtake me, though it was with a still lingering tinge of "green about the gills" that I faced an absolutely unknown and high-powered machine, with low handle-bars and high gear. On landing at Douglas Quay I found greasy roads which did not add to my comfort, but gingerly pushing the machine off I soon discovered that, like my old 3 h.p., nothing could be more docile or tractable, and, further, that the luxury of handle-bar control must be experienced to be believed by those who are as yet unacquainted with its virtues either in racing, grease, or traffic. With more than 300 miles of "all out" to its credit, and that without a loose nut or mechanical fault of any sort to be recorded save one—a broken exhaust valve—this splendid "jigger" accomplished its maiden trip, and I was more than satisfied when, at the end of "one crowded week of glorious life," it was time to make tracks for home and work again. None the less that bent and broken valve, with its ensuing loss of so much priceless time, was to be a very persistent ghost for many a long day, for, up to the moment when disaster supervened at the eleventh hour—or, to be more exact, at the ninth round—the machine had been running superbly, and, as afterwards transpired, was at the time running into a very satisfactory place.

The Touring Side of the Question.

This, though, is not the aspect of the case with which I have set out to deal, and, to return to the touring side of the question, the machine, as it stood, did not look very promising from this point of view. Short and horizontal handle-bars, a small and unyielding saddle, short wheelbase, and plain-treaded 2in. tyres, are not popularly considered to combin in making up a sound touring specification; albeit, a good luggage carrier, toolbag and accessories, and spring forks contributed in some measure toward mitigating these drawbacks. High compression, unless in the hands of inexperienced users, cannot, I think, be regarded as a disadvantage; indeed, so great is the reserve of power at one's command with a really first rate 3½ h.p. engine, that a compression higher than the average lends just that modicum of interest to driving, which is somewhat lacking in the case of the lower compression, and consequently more foolproof, engine. In the latter case, long and winding hills with trying gradients call for nothing more than ordinary ability to negotiate them, and, provided the sharp corners can be successfully steered round, the throttle can be banged open again immediately, and, no matter how long the hill or how hot the day, the machine will see its rider through.

Different altogether is the position with high compression and with no pedalling gear to assist in picking up at the critical moment, and when, after just scraping round some evil corner on two wheels and a boot, the throttle lever is nudged tentatively forward, then it is that, more often than not with a cylinder well heated after previous hard driving, the premonitory symptoms of that fatal knock call for all the skill and care at the rider's command if the climb is to be successfully negotiated

A T.T. Model as a Touring Mount.—

It almost goes without saying that there is all the difference in the world between flying up long and troublesome hills in competition when the engine is cool and the road clear and tackling them as they come in the course of a long day's ride.

In the former case the chief requirements are a well-tuned engine and the removal of all superfluous weight. In the latter, where the machine is possibly laden with baggage, the surface treacherous, and traffic abundant, "rushing" is impossible, and a set of conditions demanding skill, sympathy, and care at once arises. To those who ride a motor cycle solely as a means of transit such situations will not appeal. Their solution of the problem is a machine of "pantechnicon" proportions, embodying in its often ungainly mass a two-speed gear and free engine—encumbrances which I avoid and they consider essential. On the other hand, all who ride for recreation and amusement and expect to derive interest from the pastime will welcome the occasions when care and ability are brought into play as opposed to the mere necessity of pressing a button and allowing the machine to do the rest.

Turning to the question of comfort, experience soon convinced me that, far from entailing the discomfort anticipated, the machine was not only extremely well adapted to touring purposes, but light and handy to an astonishing degree. After an extended experience of both standard and T.T. models, and notwithstanding the fact that I am but sparsely "covered," and can realise as well as most people the meaning of a lumpy road, nothing would induce me to return to what I cannot but describe as, relatively speaking, a "dodderer's" machine. It seems to be generally admitted that the main drawbacks to be urged against the majority of "standard tourists" of to-day are starting difficulty, weight, and unwieldiness, the former being directly due to the two latter, while the outstanding advantages of such machines are their reserve of power, ample margin of strength throughout, steadiness and comfort on bad roads, and, not least important, their large luggage carrying capacity.

An Admirable Compromise.

The T.T. machine, with its shortened wheelbase, reduced weight, and greater handiness, presents an admirable compromise between the heavy and light types of machine at present on the roads, inasmuch as, while retaining the ample margin of strength, great reserve of power and speed and general solidity peculiar to the heavier type, it exhibits much of the handiness and economy of upkeep characteristic of the lightweight. The only points upon which the latter can claim superiority, viz., lower weight, easier starting, and convenience in traffic, amount to comparatively little when examined in the light of practical experience. Taking these three points in order, the difference in weight to be found between the average lightweight touring machine and the T.T. machine is hardly likely to be more than 40 lbs.—not a great deal, in view of the very much greater capabilities of the latter. The idea that high compression and starting difficulty are as inseparable as the Siamese twins has no foundation in fact, since compression can be obviously reduced to any desired extent by merely closing down the throttle somewhat and reducing the charge. Lastly, in the absence of a clutch, it would be difficult indeed to find a machine more suited to dodging through dense city traffic than the one I am describing.

Suiting the Machine to the Conditions.

In making the foregoing comparisons and in suggesting the wider use of this class of motor bicycle for touring purposes I have naturally pre-supposed suitable modifications and adjustments to carburetter, ignition, and gear ratio to meet the altered requirements and conditions of such work.

The carburetter may with advantage be fitted with a smaller jet and the standard roadster choke tube, in order to secure slow running when needed. Opportunities for mile-a-minute bursts being few and far between on most roads, the magneto may be timed a trifle later and a somewhat more vigorous spark obtained when the ignition lever is slightly retarded.

The tyres fitted to my own machine are the 2in. wired-on Dunlop, and of these I can speak in terms of highest praise. It is as difficult to pick holes in them metaphorically as it is literally, they neither puncture, cut, nor show wear to anything like the extent that previous sets of 2¼in. tyres have done, they are notoriously fast, their removal and replacement present no more difficulty than does the beaded edge variety, they stand up on and cut through grease in winter, owing to their narrow tread, and throw up a minimum of dust in summer. Unfortunately, I have kept no accurate account of their mileage, but they are probably distinctly more economical in the long run than 2¼in. covers, notwithstanding their lighter build.

A Few Special Points.

There are, perhaps, a few more points relating to this machine which will bear detailed mention.

Two great faults of the original form of handle-bar were a necessarily bent forward attitude at all times and the difficulty of steadying the front wheel in grease. These have since been eliminated by replacing the earlier pattern with a more recent design, which, while providing a crouching position when necessary, gives ample leverage in dealing with ticklish steering conditions, and at the same time makes a comfortable upright sitting position possible. The hard saddle, which can, of course, be replaced by one of more generous dimensions and better springing, is not half so formidable as it looks, and many will find, as I did, that familiarity breeds contentment! Lastly, to deal with some imaginary evils: Engine vibration is not noticeable at any speed but the very slowest, when the engine naturally tugs somewhat on the short belt, the length of drive being reduced with the wheelbase. Excessive carbon deposit and broken valves innumerable are still other popular bogies, though I have suffered no serious annoyance from either, and, in spite of tolerably generous lubrication, the cylinder and piston can be left at this time of the year for quite 1,000 miles without scraping.

In conclusion, I trust the reader will not ascribe my expressed preference for the T.T. machine to be a lust for speed as opposed to the enjoyment of legitimate touring. Fast as these machines undoubtedly are, they are yet, as I have tried to show, a first-rate combination of two types, and can jog along at touring gait with as much ease as they skip round the Isle of Man course in twenty minutes. T. T. T.

Ignition Repairs.

Messrs. Fellows and Co., 49, Hertford Street, Mayfair, W., inform us that they have a special department for the repair of motor cycle magnetos, coils, and accumulators.

Kerry's in Bristol and Sheffield.

The East London Rubber Co., Ltd., 29-31, Great Eastern Street, E.C., have opened two branch depots for the sale of Kerry motor cycles and accessories. One is at Kerry House, Furnival Street, Sheffield, the other at 101-102, Thomas Street, Bristol.

The Care of the Indian.

"Instructions for the Starting and Care of Indian Motor Cycles" is the title of a little booklet which has just been issued by the Hendee Manufacturing Co. One of these booklets is sent out with each Indian motor cycle, and can be obtained from the Hendee Manufacturing Co., 184, Great Portland Street, W.

Scandinavian Exhibition.

Mr. George Verbeke, 15, Rue du Fort, Ghent, Belgium, informs us that he is shortly going to establish himself in Christiania, and there enter into the motor cycle and motor car trade. This year there will be an exhibition in Bergen, and English firms who would care to have their interests represented should write to Mr. Verbeke.

SPARKLETS

Export Business.

The Service Co., Ltd., are doing quite a good export business. Recently they exported two Scotts, one to India and the other to South Africa, while they have also just shipped a Motosacoche to Russia.

Fresh Appointments.

Mr. A. T. Stanton, who is fairly well-known to many of our readers as a competitor in motor cycle trials, and London agent until recently for Bradbury and Co., Ltd., has now joined the firm, and will represent them in London, and the Northern, Eastern, and Western districts.

Mr. H. W. Duret has resigned his position with the Singer Motor Co., Ltd., and has accepted an appointment with the Palmer Tyre, Ltd., as West of England representative. Mr. Duret was the recipient of a handsome present and testimonial from the directors, and he is taking up his new duties with the best wishes of his many friends.

Catalogues Received.

The Prested Battery Co., Elthorne Road, Upper Holloway, N., have now issued an advanced 1910 list containing several new and useful specialities.

The Simms West End Agency.

The Simms Magneto Co., Ltd., Welbeck Worke, Kimberley Road, Willesden Lane, Kilburn, N.W., inform us that they have come to an arrangement with Messrs. G. H. Smith and W. H. Dorey, 14a, Great Marlborough Street, W., to act as West End agents for Simms magnetos.

A Progressive Business.

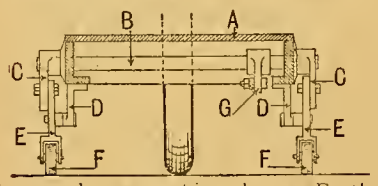
Although only established a few months as dealers in motor cycles and accessories, the Lancashire Motor Exchange, Euston Road, Morecambe, which is conducted by Mr. C. H. Hitchen, has made extremely rapid progress. The firm commenced dealing in motor cycles last September, and during the latter part of that month sold only one machine, value £38. Last month some thirty-three motor cycles were disposed of, value £800 to £900. Our readers will agree that unless the business were conducted on honest and satisfactory lines it would be quite impossible for it to increase so rapidly. Full particulars of the system upon which the exchanges are conducted will be supplied gratis.

RECENT PATENTS.

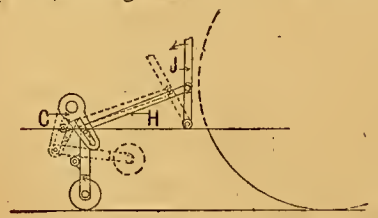
By ERIC W. WALFORD F.C.I.P.A.

Safety Supporting Device.

This device is intended for use either when the machine is stationary or travelling. Beneath the footboard A is arranged transverse shaft B, each end of which carries a slotted link C. Pivoted to brackets D carried by the



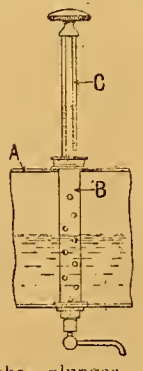
footboard are rocking levers E, the lower ends of which carry rollers F. The shaft B also carries a lever G connected by a rod H to a control lever J. When it is desired to use the support the lever J is brought into a vertical position, rotating the transverse shaft B and turning the roller-carrying levers E about their pivots, through the links C. Forward

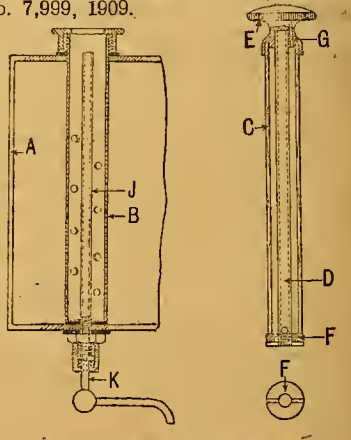


movement of the lever J brings the parts into the position shown by dotted lines, raising the rollers out of contact with the ground. The operating lever is anchored to the frame by a spring (not shown) so that the contact of the rollers F with the ground is a resilient one.—R. M. Kingsford (L. Rabe), No. 17.604, 1909.

Combined Petrol Gauge and Injector.

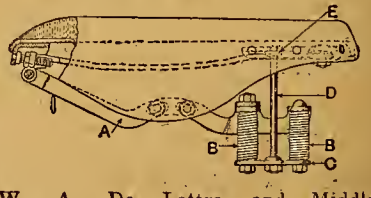
Within the tank A is secured a barrel B perforated for the free passage of the petrol. Within this barrel slides a plunger comprising a transparent tube C mounted around a pipe D by means of a knob E at the top and a nut F at the bottom. The nut F is slotted as shown, and the pipe D provided with a small hole, so that the petrol may enter the transparent tube C and find its level therein, a vent G being provided for this purpose. When it is desired to ascertain the level of liquid in the tank, the vent G is closed by the thumb or finger, and the plunger drawn up. Owing to closing of the vent G, the petrol remains in the tube C, and its level therein corresponds to that in the tank. To enable the device to be used as an injector, a pipe J is firmly secured within the barrel B, and telescopes within the pipe D. The upper open end of the pipe J is arranged to be slightly lower than the pipe D when the latter is in its raised position. If, therefore, the vent be now uncovered, the petrol will escape through the small hole in the pipe D, and drip into the pipe J, whence it passes to the desired part by way of the tap K.—J. B. Dall, No. 7,999, 1909.





A Saddle Spring Arrangement.

Each side frame member A carries a pair of tensional springs B which are bridged across by a plate C. This plate supports the rod D, which is connected to the seat proper at E.—



W. A. De Lattre and Middlemore and Lamplugh, Ltd., No. 10.357, 1909.

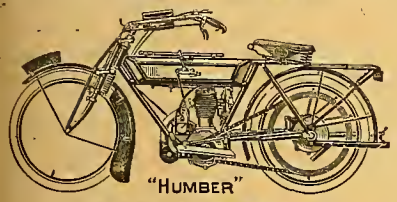
1 Humber (1909½). . £50 0 0
1 Coronet Sidecar 4 17 6

Total £54 17 6

The above sum represents the usual price of a new 1909½ Two-speed HUMBER and CORONET Sidecar. This "combination," in turn, represents the best, cheapest, and speediest method of carrying two passengers anywhere at any time. A decent car costs £500, runs twenty miles to the gallon, and averages 20 m.p.h. The aforesaid "combination" runs 100 miles to the gallon, and averages 30 m.p.h. If you are contemplating purchasing a sidecar machine, we are convinced that this "combination" will render you the best service obtainable.

£54 17s. 6d. for £42 10s.

We have decided to offer a limited number of these HUMBERS, fitted with CORONET Sidecars, at £42 10s. the pair. Remember, one only supplied in each district as an advertisement. Full specification below.



"HUMBER"

1909½ HUMBERS

Brand new. These you can hardly tell from 1910 models being fitted with improved pattern silencers, spring forks larger pulleys, Roc licensed two-speed gear, H. B. control registered tank, high tension magnetos, Dunlop tyres, oil pump operated by foot, stand and carrier, toolbag with all tools fitted to handle-bar. Fully guaranteed.

£42 10s., complete with sidecar.

1909½ Single Speed Humbers.

We have a few of these beautiful models, brand new, fitted with magneto ignition, Druid spring forks, handle-bar control. Usual price £45.

Our price **£34 10s.**

NEW 1909 ARNOS.

We have a few Brand New 3½ h.p. Models, fitted with magnetos, h.-b. control, complete with tools, etc.

List price, £45. Our price, **£32 10s.** Or exchange. Cash offers wanted.

BAT-J.A.P., 4h.p., new last month, scarcely used; 40 guineas, or near offer; cost £48 10s.—Hicks, Tregurra Terrace, St Austell.

3½h.p. Triumph, new December, 1908, not run 1,000 miles; £30; condition as new.—Saunders, 73, Howell Rd., Exeter.

NSU., 3½h.p., magneto ignition, spring forks, very fast, splendid climber, with about £5 worth extras; £16.—Reynolds, Broadway, Dorset.

BARGAIN.—3h.p. motor cycle Ascot vertical), splendid machine, good Dunlop tyres, just overhauled, thorough condition; £9; owner no further use; low build.—Apply, F. Wheeler, 6, Valis Way, Frome, Somerset.

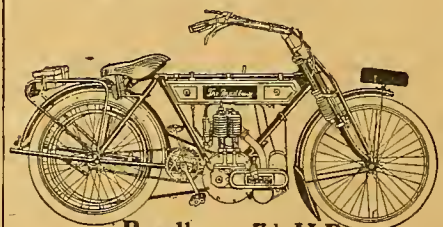
There are a few lines on this page, but the best line, and the

BEST LINE IN THE TRADE,

is the

BRADBURY

3½ h.p. MOTOR.



Bradbury 3½ H.P.

An expert opinion declared it to be ahead of anything yet turned out in the Motor World.

Owing to its special frame construction, no other Motor Cycle is as rigid, as well balanced, as steady on the road, or provides the same accessibility for repairs or re-adjustment to engine parts.

Bradbury & Co. Ltd., OLDHAM.

MOTOR BICYCLES FOR SALE.

SECTION X.

Scotland.

1 [illegible] Rex, 5½h.p., 1907, magneto, spring forks, cant lever saddle, first-class order; £16.—Bell, Crescent Dalmuir.

TRIUMPH, 1909, little used, full equipment, perfec running order; £36.—Durie, 12, Lewis Terrace Edinburgh.

3½h.p. Minerva, good condition, recently overhauled new tyres, etc.; £16.—Garner, 9, Regent Park Ter race, Glasgow.

2¼h.p. Motor Cycle, magneto, grand condition; £5 owner not a motor cyclist.—Particulars, Wilson 42, Park Place, Lockerbie.

F.N., 1910, two-speed, lightweight; immediate deliver from stock; catalogues post free.—Rossleigh, Ltd 32, Shandwick Place, Edinburgh.

TRIUMPHS, 1910 standard, or free engine models immediate delivery from stock; catalogues post free —Rossleigh, Ltd., 32 Shandwick Place, Edinburgh.

2¾h.p. Stevens Engine, 1909, B. and B. carburetter handle-bar control, good condition; £12.—Cuth bertson, 17, Union St., Edinburgh.

2½h.p. Brown, vertical engine, Longuemare carbur etter, Dunlop tyres, in good running order; £1 10s.—Emond, 37, Well St., Paisley, Scotland.

SCOTLAND'S Largest Motor Cycle Firm.—Rex, V.S. Indian, Moto-Reve, Phelon and Moore, Zenith Douglas, Roc, Griffon, we stock all these, and can supply any other make.—Alexander's Motor Exchange, Lothian Rd., Edinburgh.

SECTION XI.

Ireland and Isle of Man.

3½h.p. Rex, splendid running order; offers; exchange lightweight.—Lucas, Courthouse, Wexford.

TRICARS FOR SALE.

PULLMAN'S.—Aster tricar, 6½h.p., water-cooled, two speed; £25.

PULLMAN'S.—Wolf tricar, 4½h.p., w.c., two-speed £20

PULLMAN'S.—Steven's Tricar, 4½h.p., w.c., two speed; £20.

PULLMAN'S.—Quadrant tricar, 5h.p., twin, two speed; £22.

PULLMAN Bros., London Rd., Norbury, London.

SINGER Tricar, 9h.p., splendid condition; bargain.— Bush, Wells Rd., Bath.

4½h.p. Riley Tricar; £25, or part exchange motor cycle —Waterfield, 23, Mount St., Nottingham.

9h.p. Riley Tricar, re-painted and overhauled, splendid machine.—W., Elms House, Hammersmith.

ARIEL, magneto, three speeds; must sell, moving; no reasonable offer refused.—W., 94, Norwood Rd., S.E.

5-6h.p. Twin Sarolea Tricar, in perfect order, nearly new; £30; trial.—Taylor, 8, West Bank, Stamford Hill, N.

TRICAR, 5h.p., twin, in excellent order; £16.—Mat thews, stationer, Lower Mortlake Rd., Richmond Surrey.

3½h.p. Rex Detachable Tricar, handle-bar control £8 10s.—Particulars, 64, Sussex Rd., Stockwell S.W.

6h.p. Rex Triette, R.O.M., in good condition; £20, o exchange magneto motor cycle.—Shaw, Glenshira Grantham.

QUADRANT Tricar, 5½h.p., good condition; tria given, £20.—Chapman, 2, Ryedale, Forest Hill Rd. East Dulwich.

3½h.p. Rex Tricar, belt drive, accumulator, coil enamelled French grey; £12.—785, High Rd. Leytonstone.

REXETTE Tricar, 8-10h.p., wheel, two-speed, water cooled, seats three, grand order.—14, Ecclesal Rd., Sheffield.

3½h.p. M.M.C., Chater forecar, beautiful condition; after 7, Saturday 2.—1, Marten Rd., Chingford Rd., Walthamstow.

3½h.p. Lagonda, coach-built, Chater-Lea, handle start ing, two speeds, splendid condition; £16.—38, Frances Rd., Windsor.

£15 Each, or nearest offer.—6h.p. twin Advance, 4 h.p. Rex; must clear; want room.—St. Edmund Garage, Northampton.

GENN'S Wimbledon.—De Dion, water-cooled, Chater F frame, spring coach body, splendid order; £23. —Motor Works, Gap Rd.

WOLF Water-cooled Tricar, three speeds, free engine coach-built, Clinchers; £20, a bargain.—Chilton High St., Watford. Photo.

5h.p. Gerrard, free engine, water-cooled, three speeds tyres excellent, back steel studded, comfortable seats; £15.—Cooke, Bank House, Tenby.

5½h.p. Twin Antoine, Lows variable gear, large clutch, open frame, just overhauled; £25; going Canada reason selling.—Mayes, Whitfield, near Dover.

THE MOTOR CYCLE SUPPLEMENT

M.C.C. OPENING RUN AND EASTER TOUR.

It has been decided not to hold the opening run on March 12th as originally intended, but to combine it with the Easter Tour to Salisbury. Eastertide falling so early this year the opening run will still be early in the season. It is expected that this combination event will prove a big success, especially as the Land's End and back run for the Jarrott Cup and gold medals will take place during the holidays. Members taking part in the run to Salisbury will be able to interest themselves in the competitors in the long journey, Salisbury being on the route of the Jarrott Cup competition. Entries are rolling in for the last-mentioned event.

MORE LIGHT ON THE QUARTERLY TRIALS.

"Having read with interest the many letters appearing in *The Motor Cycle* in reference to the last Quarterly Trials, I as a competitor, riding a 3½ h.p. Bradbury, may be able to throw some light on the various points raised.

"Taking Mr. Eli Clark's letter first, he is perhaps not aware that the first two or three competitors to arrive at the bottom of Dashwood Hill had to start practically on a sheet of ice without the aid of ashes, which were thrown down after the first two or three had started, which I think he will admit gave some advantage, and, moreover, these arriving later had the undoubted advantage of riding straight up the hill. Perhaps he was one of these lucky men!

"In my case, I was the second man to start up the hill, and, unfortunately, fell, as my front wheel fouled a rut.

"Mr. W. Pratt (P. and M.) followed me, and he also fell from the same cause. We both went to the bottom of the hill again and started away from the ice-covered road, and made clean ascents, and, taking this into consideration, it must be admitted that the marks awarded are quite fair, as all the riders who came after gained an undeniable advantage.

"I note he refers to Messrs. G. Lee Evans and W. O. Bentley being awarded non-stops; this award I do not agree with, as I saw the conditions under which they stopped in Berkhampstead.

"I think the above remarks will fully reply to Mr. Perryman's letter also, although in my case I should like to say the reason of my failure on Rectory Hill was caused through a slipping belt, and not through a mechanical trouble; but I feel, had I not had this trouble, I should have been awarded a non-stop.

"I was under the impression that all competitors in trials entered agreeing to abide by the judges' decision, but it appears by all the correspondence taking place that some of the competitors wish to make rules to suit their own particular case.

"I am pleased to say I am quite satisfied always to abide by the decision of the judges, under whom I enter, and I think a word of appreciation is due to them in their great task, and that our object should be rather to assist them than to disparage them.—W. Cooper (a satisfied competitor)."

A FIVE MILE MOTOR CYCLE RACE AT GLASGOW.

Last Tuesday, the 22nd inst., the Glasgow Theatrical Sports (which had been suspended from the Tuesday of the previous week owing to a snowstorm) were brought to a successful conclusion. The Celtic Park track, which is three and a half laps to the mile, was commissioned for the events, and the day proved fine and the track dry. Mr. A. Gordon Bostock, on his new 3½ h.p. Bat-J.A.P., scored a runaway win in the five-mile motor cycle race, leading by five and a half laps, *i.e.*, about one and a half miles, at the finish. Mr. Hilton, riding a 3½ h.p. Triumph, was second. The winner's time was 5m. 34s., which, it must be admitted, was exceptionally good, considering the damp atmosphere and the small size of the track. Mr. Bostock expects to ride his new mount in the forthcoming Tourist Trophy Race, and, judging by the speed he accomplished on his first public appearance on it last week, he should prove a competitor to be reckoned with. By the way, Mr. Bostock's machine is fitted with the 1910 pattern Amac carburetter with adjustable jets, and he reports that it is most satisfactory, combining easy starting and high engine speed. He used a 3½ to 1 gear, and the engine is an ordinary standard pattern 85×85 mm. An unusual position has been adopted for the exhaust valve lifter lever on this particular Bat machine. Instead of being placed immediately under the handle-bar grip, it is in front and at a level height with the handle-bar. This position proved to be most satisfactory for the Celtic Park track, as a racer must sometimes raise the valve to pass another competitor on the banking, the track being narrow, and it is most necessary that the lifter lever should be in the most convenient position.

A. G. Bostock on his 1910 mount—a 3½ h.p. Bat.

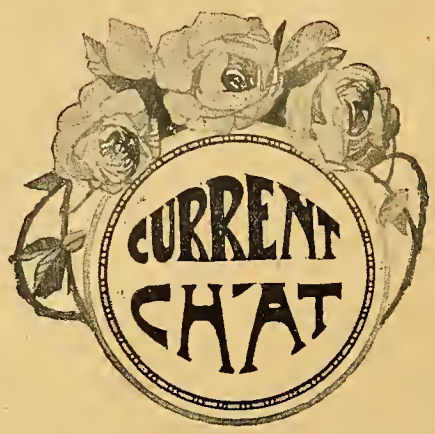
TOURIST TROPHY RACE.

H. H. Bowen has decided to ride a Bat motor bicycle in the T.T. Race, and A. J. Moorhouse advises us that the mount he has selected is a twin-cylinder Indian.

Further entries for the T.T. were received last week as follows:

P. Brewster (3½ h.p. Norton)
J. Jones (3½ h.p. Triumph)
H. Rem Fowler (1 machine)

The above bring the total number of entries to thirty-four.



Police Traps.

We have received information of a police trap in Willesden Lane, working from the railway bridge to the Prince of Wales public-house.

Motor Cycle Competition "down under."

A reliability trial from Timaru to Dunedin—a distance of 258 miles—was promoted by the South Canterbury (N.Z.) Motor Cycle Club on December 25th and 28th. The trial was divided into two sections—one for trade riders, the other for private owners. The former was won by G. B. Brown and the other by H. Mayo, both riding 3½ h.p. Triumph machines. Moreover, another rider of a Triumph—C. E. Hassell to wit—was first in the petrol consumption test over the same course.

How Long will an Air-cooled Engine Run?

On January 24th, at 10 a.m., we read that a 1910 Yale 3½ h.p. stock motor bicycle was started in the window of the Oberwegner Motor Co.'s store at Toledo, Ohio, and ran continuously without one stop, and without fan or other cooling device at an average speed of 1,285 revolutions per minute until stopped at 10 p.m., Saturday, January 29th, a period of 132 hours. A cyclometer applied to the rear wheel, we are told, registered 2,794$\frac{1}{10}$ miles. After the test three experts examined the machine carefully, and found it in perfect condition, motor free, and compression and bearings perfect.

M.C.C. Team Competition.

It is a strange but true fact that no club other than the Motor Cycling Club and the Coventry and Warwickshire Motor Club has won *The Motor Cycle* Cup in the above competition, although it is now six years since the competition was inaugurated. There has, however, been some very close running for the cup. For instance, the St. Albans Club (now the Herts County A.C.) had hard lines last year as the team started a man short, but the other five gained all possible marks. The Birmingham M.C.C. also came near to winning on one occasion, one of the team losing marks for arriving home before the minimum time limit. It was afterwards found that this had deprived the Birmingham team of the cup.

A Measured Furlong.

A police trap is in working order on Shooter's Hill Road, one furlong, the point being near Kent Villas.

A Leader in America.

We regret to announce that F. P. Prial, publisher of the American *Motor Cycle Illustrated*, died in New York on Monday, January 31st, of typhoid.

A Return to Flat Belts.

The very latest from the Hendee factory is a 4 h.p. single-cylinder Indian with free engine clutch and gear reducing rear pulley, the transmission being by means of a 1½in. flat belt. It is claimed to be the only perfect belt drive ever produced. The driving pulley is 8 inches in diameter, and the driven pulley 10 inches. The high speed at which the belt runs and the large gripping surfaces are considered to be the main factors for the success achieved by this new model during the 4,000 miles it has been tested on the road. For the present this machine will only be marketed in America.

A Hill-climb for Standard Machines.

The open hill-climb to be arranged by the Bradford M.C.C. on June 25th will be a thoroughly sporting event, and we are specially asked to mention that ample classes will be provided for the amateur with his standard machine.

Motor Cyclist taken for an Anarchist.

A Russian correspondent informs us that at the time of the Czar's visit to Italy extraordinary precautions were taken to ensure his safety. A motor cyclist, residing in one of the towns on the route through which the train carrying the Czar passed, had the misfortune, when trying his motor cycle on the stand, to have the top of the cylinder blow off with a loud explosion. No one was hurt, but the next day the motor cyclist's house was visited by the police, his typewriter and papers were removed, and he was put under arrest and kept in prison for seventeen days. All this was occasioned by an explosion which the police suspected had something to do with an anarchist bomb. Of course the motor cyclist received no compensation from the police when they found out that they were mistaken, and the only thing that they could possibly bring against him was that he had once sold a motor cycle to a suspected anarchist and had visited the house to collect the money.

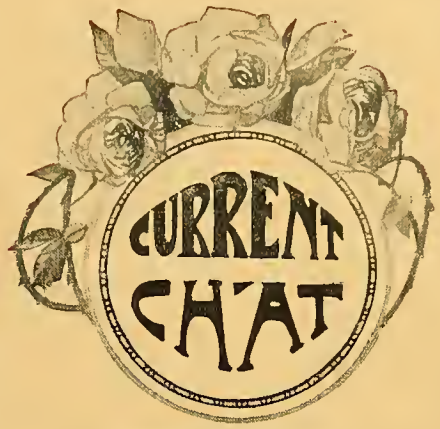
Feb. 28th	...	...	6.35 p.m.
Mar. 2nd	...	...	6.39 ,,
,, 4th	...	...	6.42 ,,
,, 7th	...	...	6.47 ,,

From the Atlantic to the Pacific Coast by Motor Cycle.

We have a most interesting article in the press entitled "Across the American Continent on a Motor Cycle," by Stanley Bowmar, and we expect to be able to publish the first instalment next week. The author describes in a bright and breezy style his many privations and exciting experiences during the 4,000 miles journey from the Atlantic to the Pacific coast, including an encounter with rattle snakes, a night in a dilapidated ranch house, lost in the prairie, a blinding snowstorm, a forty-mile walk for petrol, several miraculous escapes from being run down by overland expresses whilst riding between the rails, his acquaintance of cowboys and shepherds, a long railway journey in an empty ice-box, and the final effort to San Francisco.

A.C.U. Legal Department.

The benefits of the Legal Department to A.C.U. members were recently exemplified in the case of a member of the Oxford M.C.C. The motor cyclist in question was riding his machine near Banbury, and on the road he passed a horse and cart. The driver of the latter was evidently not attending to his business, for the horse commenced to prance about, and, in endeavouring to run alongside and catch the reins, the driver was unfortunately knocked down and the wheels of the cart passed over and killed him. His relatives obtained £100 compensation from his employer under the Employers' Liability Act, whereupon the employer's insurance company, having paid the claim, entered an action against the motor cyclist for the recovery of the amount paid out to the relatives of the deceased, on the ground that the noise made by the passage of the motor cycle constituted a nuisance on the highway, and that the rider was responsible. As the point involved generally affected the interest of motor cyclists, the A.C.U.'s solicitor was instructed to contest the case, with the result that the plaintiffs have since withdrawn their claim, paying all costs. Without expert legal defence the motor cyclist would probably have lost the case.



Neuchatel Hill-climb.

The coming summer will witness a repetition of the Neuchâtel hill-climb on the Chaumont route, the Union Motocycliste Romande having entrusted the Berne section with the organisation of the event.

Accessory and Equipment Issue.

The issue of *The Motor Cycle* for March 14th will be a special accessory and equipment number, and will contain specially illustrated descriptions of practically every known accessory on the market, including tyres, riding apparel, lamps, and electrical appliances. We venture to think that this special issue will be of considerable interest and service to motor cyclists at this time of the year, most of whom are contemplating the purchase of one or more of the numerous articles which will be dealt with. Although the number of pages will be necessarily very much increased, the price of the issue will be one penny as usual. Motor cyclists should make a point of ordering this number at once to avoid disappointment

Motor Union Meeting.

The monthly meeting of the General Committee of the Motor Union was held at the Union's Offices at Caxton House, Westminster, on February 23rd. In the absence of the chairman, Mr. Joynson-Hicks, who is at present in the South of France, Mr. C. H. Dodd (vice-chairman) presided over a well attended meeting. In presenting the report of the Finance Committee, the Chairman drew attention to the very satisfactory increase in the receipts from individual members. Of these over 9,000 are now included in the membership of the Union. The Legal Committee reported that they are considering proposals for securing the proper lighting of all vehicles and cattle on the highway at night. The Motor Cycle Committee is still in communication with the Army Council on the subject of the organisation and training of motor cyclists with a view to their assisting the military forces in time of national emergency. By arrangement with the Wiltshire County Council, the M.U. special road signs are to be erected at dangerous places throughout the county of Wiltshire.

(SEE ALSO PAGE 173.)

CLUB NEWS.

(SEE ALSO PAGE 173.)

Redcar Motor Cyclists Unite.

A motor cycle club has been formed for Redcar and district. All readers residing in Cleveland are invited to send their names and addresses to the secretary, Mr. F. C. Jones, 30, Vansittart Terrace, Redcar.

Middlesbrough and District M.C.C.

The committee of the above club met on Monday evening last at headquarters, and one of the main reasons was that no definite word had arrived from Mr. Scott *re* his lecture planned for February 23rd. Under the circumstances, it was decided to postpone the lecture. It now transpires that Mr. Scott's telegram had been misdirected, and had been delivered to a wrong address. It is to be hoped that another date can be fixed, as the event has aroused much interest locally. The committee also decided to hold the following events during 1910: Opening run, Richmond (Yorks), 200 miles reliability trial for Gjers Cup, fuel consumption trial for cup to be presented by Mr. Stanley Sadler, three hill-climbs, team trials, balloon race, paperchase, inter-club meets, Whitsuntide tour to Scotland, and August tour to the southern and western counties.

Essex M.C.

The A.G.M. will be held at the Great Eastern Hotel Liverpool Street, E.C., on Tuesday, March 8th, commencing at 8 p.m. Notices for the agenda must reach the hon. secretary by first post to-morrow (Tuesday).

East Lancashire M.C.C.

At a meeting last week it was decided to hold fortnightly club runs, and to join in the annual meet of Northern motor cyclists at Richmond, Yorkshire, on Good Friday.

Motor Cycle Club for Redditch and District.

To-morrow (Tuesday), at 8.30 p.m., a meeting is to be held at the Warwick Arms Hotel for the purpose of forming a motor cycle club for Redditch and district.

Westmoreland Motor Cycle Club.

The above club has recently been formed. The membership had reached forty last week, and is steadily growing. It has been decided to affiliate to the Auto Cycle Union. The subscription for the first year is 7s. 6d. (badge inclusive). The hon. secretaries, Messrs. C. B. Robinson and A. Ruthven, Kendal Green, Kendal, will be pleased to hear from readers interested.

Ayr and District M.C.

On Thursday evening last Mr. Quintin Clark submitted his "Impressions of the Five Days' Scottish Reliability Trial" to an appreciative audience of members and friends. He described in detail the route followed, his humorous sallies and excellent limelight illustrations providing a most enjoyable evening. The next lecture takes place on the 9th March, when Mr. J. Robertson will deliver a paper on "Magneto Ignition."

Glasgow M.C.C.

At the A.G.M. last Thursday, the president, Mr. D. S. Baddeley, occupied the chair. The secretary's report showed that there had been a decrease in membership of five since the previous year. The financial statement for the year showed a small decrease in the credit balance, due chiefly to expenses incurred in sending competition teams to Edinburgh. The report and financial statement were adopted, and the officials elected. The competitive events this year will include two hill-climbs, a flexibility trial, speed-judging contest, twelve hours' reliability trial, petrol consumption test, and probably a gymkhana.

FUTURE EVENTS.

Mar. 16—(Wed.) British Motor Cycle Racing Club Meeting at Brooklands.
" 25—General Meeting of Northern Motor Cycle Clubs at Richmond, Yorks.
" 25-28—M.C.C. Opening Run. Easter Tour to Salisbury. Jarrott Cup Competition.
" 25-28—N.W. London M.C.C. and Herts. County A.C. Inter-club Trial to Harrogate and back.
" 28—Brookland A.R.C. Easter Meeting (two events for motor cycles.)
" 30 to April 2—Exhibition of Motor Cycles, at Leicester, Association Hall.
Apl. 13—(Wed.) B.M.C.R.C. Meeting at Brooklands.
" 20—A.C.U. Second Quarterly Trial.
" 27-28—Brooklands A.R.C. Meeting.
" 30—M.C.C. Members' Hill-climb.
May 4—B.M.C.R.C. Meeting at Brooklands.
" 13, 14, and 15 (Whitsun)—M.C.C. London-Edinburgh and London-Edinburgh and Back Runs.
" 26 (Thursday)—International Motor Cycle T.T. Race in the Isle of Man.

Scarborough and District M.C.

Mr. H. Frain, Snainton, S.O., Yorkshire, is now the hon. secretary of this club, and all future communications concerning the club should be addressed to him.

Doncaster and District M.C.C.

At a meeting on the 23rd inst., a club was formed as above, and officers and committee appointed. Another meeting is arranged for to-morrow (Tuesday), at 8 p.m., at the Prince of Wales Hotel, Baxter Gate, for the formation of rules and to enrol new members. Will riders interested kindly attend or forward names and addresses to the secretary, Mr. Geo. F. Stafford, 7, Baxter Gate, Doncaster.

A Proposed Club for Southport and District.

A meeting was held last Thursday, the 24th inst., for the purpose of forming a motor cycle club for the above district. Motor cyclists not notified, and wishing to join, should communicate with either James F. Reid, 87, Liverpool Road, Birkdale, or R. Holford Jones, 9, Westbourne Road, Birkdale.

Walthamstow M.C.

An interesting lantern show has been arranged at headquarters, Rose and Crown, Hoe Street, on Wednesday next, at 7.30 prompt. Members are asked to attend in full force, together with lady or gentleman friends.

The opening run has been fixed for Saturday, April 2nd.

INTER-CLUB COMPETITION AT EASTER.

Reference has already been made in these pages to the inter-club competition which will take place during the Easter week-end between the North-west London M.C.C. and the Herts County Automobile Club (Motor Cycle Section). The competition will be run for a handsome silver cup presented to the Herts A.C. by the Service Co., Ltd., for an inter-club team trial from London to Harrogate and back. The hill-climb on the Saturday, which was to be held on Sutton Bank, will not take place on this famous acclivity, as the surface (so the Harrogate and District M.C.C. reports) is too bad. But we understand the latter body has found another hill, which, until the actual event, will be kept secret from the competitors.

The Service Silver Challenge Cup, presented to the Herts. County A.C. (motor cycle section) for an Inter-team Competition.

At a committee meeting of the North-west London M.C.C., held last Wednesday, it was decided to award silver cups and medals to the successful competitors, in addition to the Service Challenge Cup, which is illustrated herewith. A special cup will be awarded for the hill-climb on March 26th.

Motor Cycle Taxation.

A LETTER which we publish this week is sufficient apology for pointing out, as we have already done on several occasions, that the motor cycle tax *per se* is an injustice in comparison with other pastimes and luxuries which remain untaxed.

For example, it seems somewhat unfair to tax a motor cycle rider £1 per annum for the use of a machine which does practically no damage to the roads and to allow the owner of a hunting or saddle-horse to go scot free. Speaking broadly, the average horse used for hunting or saddle exercise is worth more than the average motor bicycle, and inflicts considerably more damage on the road surface than the pneumatic-tyred motor cycle. We are not grumbling at the amount of the tax, neither should we like to say that motor cyclists should not be taxed at all. We think every motor cycle owner is willing to pay for the pleasure he derives from the pastime, and also to contribute towards the maintenance of the roads on which he rides, but he naturally feels indignant at being singled out for taxation.

Those who can afford to pay £50 or £60 for a motor cycle do not feel the £1 per annum tax, but there are thousands of riders who do not pay anything like that amount; in fact, second-hand motor cycles can be bought in good riding condition at almost any price from £10 upwards, and the owners of these machines complain not without reason. They say if they have got to pay 20s. per annum for the right of using a motor cycle, in addition to 5s. for driving licence and 5s. for registration, owners of saddle-horses, for instance, should be mulcted to the same extent.

Road Dangers at Night.

IT appears that the steps taken by the Auto Cycle Union to endeavour to get the local authorities to enforce a regulation compelling drovers to show a coloured light when driving cattle or sheep after dark on the highway have met with ridicule in many cases. It is really astounding the short-sighted policy of some men who are supposed to consider especial cases and issue byelaws when deemed advisable. With so many accidents happening in different districts solely through the absence of a warning light, one would imagine that the authorities would regard the matter with a little less hilarity, and endeavour to find some solution of the trouble. Their one idea seems to be that motorists desire every vehicle and obstruction to exhibit a warning light so that they (the motorists) may travel faster in the dark. This is an entirely wrong idea, and all we can say in reply is that it is our fervent wish that soon county and district authorities will be composed of men capable of considering the question impartially from every standpoint. Judging from the position assumed, it does not seem to matter greatly to them whether the lives of His Majesty's subjects are endangered or not. Their refusal to take up the matter in a proper spirit amounts to nothing short of neglecting the public safety. If in exceptional circumstances it is necessary to drive cattle after dark, it is no great hardship for the drover to exhibit a warning light, if only for the safety of the cattle! Owners of cattle cannot, and will not, see the matter in this light. They seem to prefer to take the risk of their property being damaged, and then take action in the courts, knowing that they will be sure to be favoured in the verdict.

ACROSS THE AMERICAN CONTINENT ON A MOTOR CYCLE

By Stanley Bowmar.

WHAT one sees of a country from the blurred windows of a railway carriage has to me always seemed unsatisfactory. Especially was it my desire when in the United States some time ago to make something more than a nodding acquaintance with the people of the Far West, and that was the reason why I decided to cross from the Atlantic to the Pacific Coast on a motor cycle. Had I had experience (I did not then know even the first thing about motor cycles, never having ridden one), I should doubtless have rejected a machine so cumbersome and unsuitable for the roadless West in favour of a strong bicycle, which could have been carried across fords, sand draws, and deserts.

Friends, some of whom knew a little of the West, were loud in their warnings of dangers and difficulties, and other folk, who, as I afterwards discovered, drew considerably on their imaginations for their knowledge of western life, were even more insistent in their tales of woe inevitable. They spoke of devastating tornadoes and blizzards, dangerous rattle snakes, bears, wolves, and mountain lions, and they discussed with greatest gravity the question as to which make of revolver would most effectively serve me in the wild and woolly West.

Just what did happen on that eventful journey will be told in this article.

The Start from Buffalo.

I left Buffalo, N.Y., on June 12th, and, following the main railway route *viâ* Cleveland, Chicago, Omaha, and Grand River, turned 100 miles south to Denver, Colorado, this section (roughly half) of the 4,000 miles journey being completed at the rate of 80 miles a day. Without mishap, should I say? Not exactly. On roads so wretched as those of even the middle and what might be termed the near western states accidents are inevitable to the motor cyclist, who, much against his own inclination, speedily becomes an acrobat of no mean accomplishments. Through skidding on slimy roads and coming to grief in yawning cart ruts I made the acquaintance of the bottom of more than one ditch, the centre of hedges innumerable, and one night near Rodger (Iowa) was pitched headlong over the side rail of a bridge into the creek below. Yankees, you know, have a penchant for improvements, for things "just a little different," and their small bridges certainly achieve the desired result. Instead of the earth (metalled roads are rare) being levelled up to the bridges, the first plank on either side is usually four or five inches above the level of the road—an arrangement quite unsuitable for fast night riding.

It was frequently impossible, especially in Nebraska, where population became sparser and when the motor worked unsatisfactorily, to reach a town or a ranch until late at night. One stormy night between Omaha and Grand River the only available accommodation was an old straw stack, and on another occasion in Nebraska (at Ogallala) an hotel keeper whom I knocked up in the early hours of the morning refused to have anything to do with me, accusing me of being a hobo "wanted" by the district police. Certainly appearances were against me, as they frequently were

Route followed by the writer on his trans-continental ride of 4,000 miles. Several hundred miles were ridden between the railway lines.

Across the American Continent on a Motor Cycle.—

Bespattered with mud and oil, no doubt I presented a by no means fascinating appearance.

My First Acquaintance with Rattle Snakes.

I made my acquaintance with rattle snakes when lost in a dreary stretch of prairie between Fort Morgan and Duelle (Colorado). Their warning rattle was at first as startling as it was frequent. One, objecting to the intrusion of the front wheel, made a vicious stab at my right leg, but before he had curled up ready for the spring I jumped aside to a safe distance.

Bridge across the Great Salt Lake.

Enumeration of my motor troubles thus far would weary even the most enthusiastic devotee of the little self-propelled machines. My motor cycle was a 1906 pattern, and it, as we all know, was very, almost totally, different from those now on the market. At the same time, it was not that my American machine—a 2¼ h.p. Merkel—was altogether unsatisfactory. There was ample room for improvement in it, goodness knows (and so do I), but in myself as a motor mechanic there was still more scope along lines identical. My ignorance of motors and their eccentric, tricky ways magnified every insignificant motor mole hill into a mountain that frequently took half a day—sometimes a whole night—to negotiate. I had to work hard, long hours to average 80 miles a day to Denver (2,000 miles, roughly), but half my energy went in buying experiences at a stiff price. The belt (an inch flat one) troubled me continually, and as the dry batteries on which my ignition depended—well, so as not hopelessly to prejudice whatever slight chance I may still have of admittance to the Land of Gold Pavements and Perfect Roads, I always endeavour never to think of dry batteries, the thought of them does so sorely tempt me to blaspheme.

I worked fourteen weeks in Denver. Autumn was fast slipping into winter when I steered again northward to intersect my guiding line, the Union Pacific Railroad, at Cheyenne. My excursion immediately developed into a race over mountain and desert with the dread season of storms and all that it connotes in the bleak spaces of the West.

The absence of decent roads, or of roads of any description for that matter, is a feature of the country districts in the States that cannot fail to impress itself on every cyclist or motorist. Even in the productive Platte Valley, which stretches for between 500 and 600 miles from Omaha to Denver at the foot of the Rocky Mountains, one finds only cart tracks, frequently unfenced; in fact, it would take no great effort of imagination to think of them as the original trails of the herds of buffalo which twenty years ago roamed the valley. Ample grants of money are made each year for the improvement and maintenance of the roads, but these sums find their way, in characteristic Yankee fashion, into the pockets of successful political wire pullers, road inspectors, and other officials, whose principal employment appears to be the careful manipulation of the public funds to their own advantage.

Steamboat Rocks, which stand out like the bows of gigantic liners, overlooking Echo Canyon, not far from the fertile Utah Valley.

Leaving Denver, riding by the foothills of the snow-capped Rockies, I was soon wallowing in mud. In passing a country cart a rut forced me to shave pretty closely to the vehicle. The irate Yankee yokel bawled an angry invitation to a fight. "I guess I'll take a fall out of yer," he yelled. But as I knew only too well that I should get plenty of these within the next three or four weeks, I merely opened the throttle a little wider, and left him gesticulating in the rear. Road hogs are not, it should be remembered, confined to motorists. As if to prepare me for the more adventurous part of my journey, that same evening I was pitched over a barbed wire gate. Out West wire gates, where

Across the American Continent on a Motor Cycle.—

there are any gates at all, are common. Usually, however, to make them visible at night, an empty sack is hung over the top wire. On this one the sack was absent. Bowling along merrily at a fifteen miles an hour pace, following a prarie trail that paralleled the railroad, and watching the perky, snappy little prairie dogs as they scampered to their holes, I did not notice the wire until too late to avoid a collision. A treble or quadruple somersault (in the excitement I lost count) landed me over the gate and into a rut. Result: Torn knickers, skinned knee, and a ripped front tyre cover.

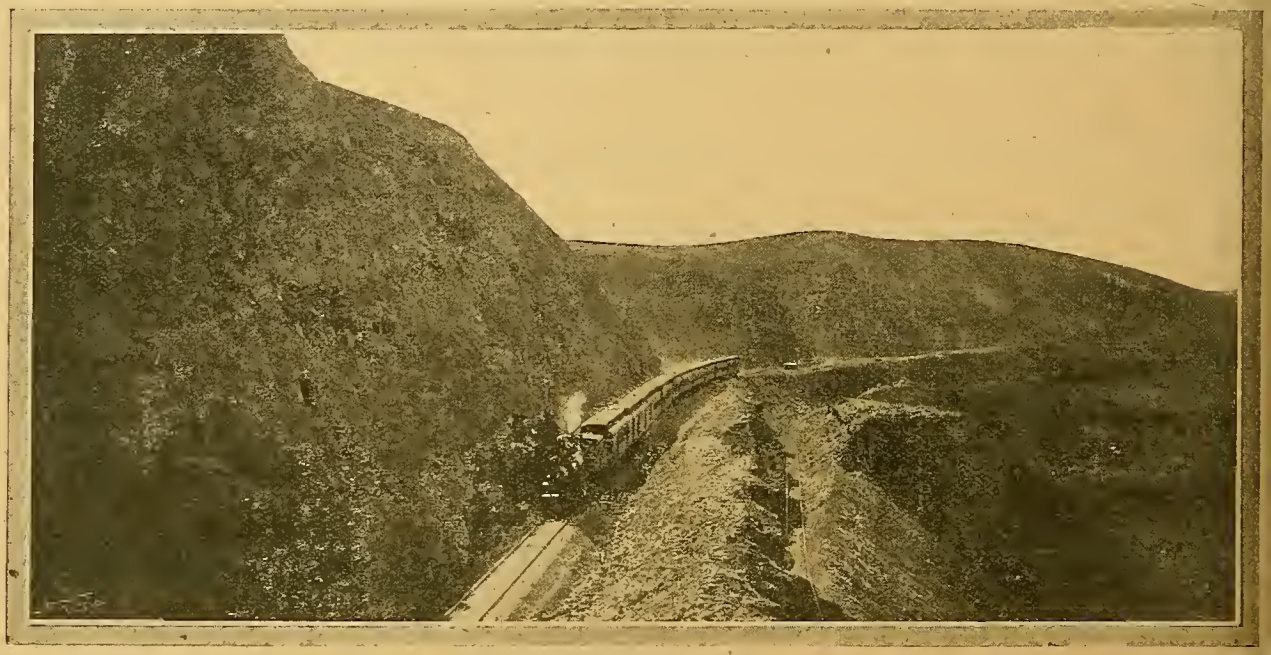
The damaged tyre forced me to put up for the night with the railway section man and his wife at a little siding called Dover. It is strange how in a long ride, where so much depends on the stability of one's machine, the mind becomes concentrated on it. Frequently in a fall, when I have felt myself gyrating through space, a thought has flashed through the mind, "What will be bent or broken on the motor this time?"—not "What sort of a rock shall I strike?"

The petrol supply was a constant worry, but of meals I soon became quite careless.

The brilliancy of the headlights on the American railway engines was remarkably illustrated at Dover. From Denver there is a steady up grade. The last twenty miles of line is perfectly straight, and for that distance the lights of the mail trains could be seen quite distinctly. It is no exaggeration to say that the clear, concentrated glare of the electric headlight, attached high on the funnel and reflected on the rails, enables the driver to see the track better at night than in the day time, provided, of course, he is not asleep.

A Choice of Two Routes.

At Cheyenne at noon next day I struck the Trans-Continental Railway line. Not so long ago this little town, now as safe for the stranger as any secluded English village, was a garrison town for the troops who guarded the mail coaches from the Indians of the Nebraskan plains. There are several famous battlefields in the neighbourhood, but, instead of relating stirring stories of the wars with the redskins, a townsman whom I met in the hotel preferred to talk of the irrigation schemes which are turning the Platte Valley into one of the finest agricultural areas in the world. Huge irrigation canals have wrought such wonders that vast areas which have practically no natural rainfall now produce more than districts that have, and always have had, a good one. Former arid wastes that were in sole possession of a few lean prairie dogs and jack rabbits are now studded with prosperous farm houses. There is not the slightest doubt that if any American were to relate in a London club one half of what has been accomplished by irrigation in Nebraska and Colorado his statements would be received with indulgent smiles and considerable dubiousness.



An "Overland Limited" out West.

There are two routes over the Rockies. One follows the romantic, glittering steel rails of the Harriman Railway; the other, a shorter but an utterly lonely trail, is by way of the telephone lines which here diverge from the railway. Opinion was divided as to which route was preferable. The most encouraging report from at least a dozen enquiries at Cheyenne was that both were bad—"both impassable for a motor cycle." A spin of a coin sent me by the telephone route. I have a notion that my usual ill-luck in games of chance once more operated in my disfavour. How many miles I played the part of the pushing donkey I cannot say. The Chinese in measuring distances discriminate between flat and mountainous country; a li on a plain is longer than a li in the mountains. Calculated Chinese fashion I must have walked at least 101 miles, although a British surveyor would probably credit me with no

Across the American Continent on a Motor Cycle.—

more than the last four miles to the summit. Frequently the trail, at best totally unsatisfactory, simply disappeared. The number of ridges to be scaled seemed interminable. The summit of each one (that had once promised to be the last) revealed another, and yet another, until I was convinced that mountaineering with a motor cycle was something more than a failure.

Some compensation was to be found in a glorious view from one of the ridges. To the east there was the Nebraska plain, intersected by a tiny streak which represented a great volume of water, the Platte River, as it wound its circuitous way to join the Mississippi, 600 miles farther east. To the south, along the range, but below the timber line, stately and majestic pine forests clothed the mountains, and from where I stood there was dimly audible the sag and sigh of the wind through these mighty timber fields.

Met One Person in a Whole Day's Ride.

About noon I met a waggoner—the only person I saw that day—who was carting winter provisions to an isolated ranch. As we lunched together he confided that in his younger days he had been a Chicago newspaper man. The gay life of Jack ashore had driven him from the Windy City to western ranching. He was still interested in the press.

"Struck the *Denver News?*" he asked me. I admitted that the red ink headings (red ink headings are a feature of the yellow press in the West) had drawn attention to the *News*.

"Well," said he, "one of those telephone wires belongs to the Hearst Syndicate papers. The *News* is one of them. The syndicate telephones news right across the continent, and the Hearst papers call this special line 'the longest leased wire,' but the opposition folk refer to it as 'the longest leased liar.'"

He was a gay, good-hearted, devil-may-care, highly educated fellow, typical of hundreds one meets in the Western States. No spectre of the future troubled him, and until all the saloons were closed (an unlikely happening) it was useless, he said, his returning to city work

Darkness had set in before I reached Laramie, the lonely little capital of Wyoming, the great cattle State. The boulder-strewn canyon track which led from the summit was fit for no vehicle yet invented, and the attempts I made to ride, slowly and gingerly, invariably ended in disaster. Once I was pitched thirty feet to the bottom of a gully. Fortunately, there were no rocks on the damp, spongy stream bed, and I escaped with nothing worse than a cut and bruised ankle. Had the machine followed me over the bank it would probably have been totally wrecked.

The Real West and the Typical Cowboys.

Nowadays the real West—everything typical of the old days—is on the "other side of the Rockies." Laramie, therefore, was my first city of the wilds. About its saloons one sees the typical cowboys, true sons of the prairie—tall, slouching, brown skinned fellows, coatless and vestless, their trousers held up by belts, and their rough shirts open at the neck. Wide brimmed felt hats topped off these breezy men of the open. Emphasised by a string of lurid oaths, one of them remarked that theirs was a careless, rollicking life. I didn't dispute the fact. Judging from their performances at Laramie, I should say their specialities were swearing and spitting. They may be crack shots with a Colt's; I saw no demonstration, but I can vouch for the fact that they can drown a fly in tobacco juice at from ten to twelve feet!

But Laramie is not only a rallying ground for the roughest type of ranch workers. It has been laid out and built with an eye to the future. Its broad streets run at right angles, and the jerry-built, ramshackle huts and saloons have given place to substantial buildings. Eight thousand is its population, yet it has a university that would do credit to any Eastern city. Not to be behind the times, a flourishing garage is very much in evidence!

(To be continued.)

One of the wonders of Nature. A remarkable rock on the Transcontinental route which has been aptly named "Natural Fort."

ROTARY ENGINES FOR MOTOR CYCLES.

THE above subject was brought to my mind as I was thinking of last year's events in the motor cycle world, and of the great success the Gnome engine has had in connection with flying machines. Most of us will remember the Barry revolving engine which was exhibited at the Stanley Show of four or five years ago, and some of us can recall the experimental Lamplough motor brought out shortly after.

It may be that these engines, like many good inventions, were before their time, but I think their non-success at the time was due more to the design than to the principle on which they worked. They both differed from the latest Gnome engine in many important points, although the main idea—to save weight and give a greater cooling surface—was the same. There is no doubt this type of engine can be made to work efficiently and give reliable running, and its suitability for motor cycle work will soon be tested.

A 5 h.p. Motor weighing 20 lbs.

If the weight can be brought down to about 4 lbs. per horse-power and still have the working parts as strong as is needful, then there is a good claim to be made for its adoption. If an engine could be made to weigh about 20 lbs. complete and give 3 to 5 h.p., the whole design of the motor cycle would undergo a great change. Frames, wheels, etc., could be built lighter, and this would make for longer tyre wear and more economical petrol consumption, which would mean less dead weight to carry in fuel and tank.

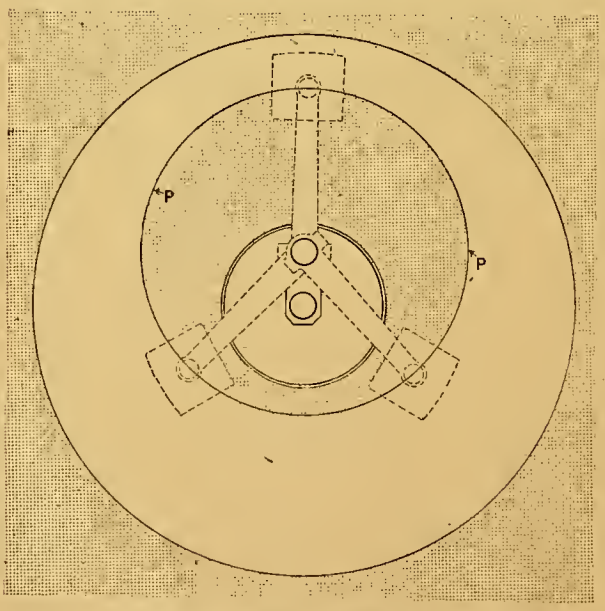


Fig. 1.—PP denotes the path described by the pistons of a rotary engine with fixed crank shaft.

What a splendid prospect, and all the more so, as the gate which leads to it has been opened by the makers of the Gnome engine, and it is now within our reach. A lightweight yet powerful motor is just as essential to the motor cyclist as it is to the aeroplanist, and it is because it has never been produced that the present-day design has been accepted, just as the motor-carist has had to accept the sliding gear—for want of something better. We are always moving forward, however, and no doubt some day the motor-carist will get his ideal gear and we our ideal engine.

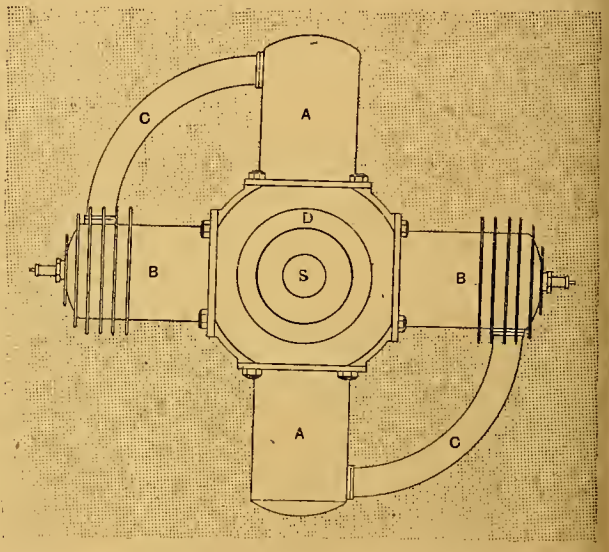

Fig. 2.—Diagram of an early type of rotary engine called the "Barry." AA, pumping cylinders; BB, working cylinders; CC, induction pipes; D, belt pulley; S, fixed crankshaft.

I do not say that the revolving cylinder engine is the ideal or even near it, but, in my humble opinion, it is as near to the internal combustion turbine as we shall ever get.

No matter how this question is regarded, we must get certain functions and conditions embodied in a turbine not at present in its steam prototype. That is, we must have means to draw in, compress, and expel the gases, and I think these operations, as performed by the movement of the piston or cylinder, are not likely to be superseded. Some petrol turbines have been designed on the lines of the Parsons, but they require another complete plant to compress the air, etc., and they cannot be cooled without a great deal of complication.

Rotary Engines for Motor Cycles.—

In the revolving cylinder type ot motor you have a far better balance of pistons and connecting rods than is possible in a stationary cylinder engine, because the pistons and rods revolve all the time at a gradually increasing and decreasing rate of speed, there being no sudden stopping and starting. This will be seen by glancing at fig. 1, which shows the course the pistons take during one revolution of the motor.

The Barry engine, which was exhibited at the Stanley of November, 1904, had two opposed working cylinders fitted on one crank chamber, and two opposed pumping cylinders, as shown in fig. 2. The lubrication caused the greatest difficulty then, though of course both the design and materials were not what are now available, and so everything was against it.

The Lamplough Rotating Engine.

The Lamplough was of the revolving type also, only more complicated and without the balancing advantages which the other had. It worked on the four-cycle principle, and was air cooled. Fig. 3 shows an end or valve view of the arrangement. A number of cylinders were clustered round a stationary shaft with the valves at one end. Every cylinder had a crankshaft of its own, which was geared to the main shaft by bevels. No particular advantage seems to be gained by this method, against which were the extra complication, extra cost of manufacture, and, I should think, noise made by the bevels. I do not think there were many engines made of this type, and nothing has been heard of them for some time.

Fig. 3.—Diagram of the Lamplough rotary engine. A, cylinder; B, valve; C, tappet levers; D, timing gear case; E, fixed crankshaft.

The Gnome Seven-cylindered Engine.

The Gnome engine is a third type that has been brought forward, and seems to be the only successful one. When first introduced most of the critics were against it on account of the oiling arrangements, which they did not think satisfactory. Others said there was no need for such a novel type of engine. Any difficulties which showed themselves have been overcome, and the one which the experts pounced upon as likely to be the most troublesome, namely, the lubrication, has proved to be non-existent. Everyone who takes an interest in following the progress of the aeroplane knows how successful Mr. Farman and others have been with the Gnome, so there is no need to say anything further here. It has always been made with seven cylinders, but for the bigger powers fourteen cylinders are to be tried. Of course, this would mean excessive complication when only 3 or 4 h.p. was required, so I think four cylinders would be the limit for motor cycles.

All the trunk piston rods in the Gnome drive on to a one-throw crankshaft. The mixture is fed through this shaft, which is hollow, into the crank chamber, and passes through inlet valves fitted in the heads of the pistons into the combustion chambers. The balancing of the valves has been the greatest trouble the manufacturers have experienced, and, although they have succeeded in the aeroplane motor, I think a lot of experimenting will be required before they can say the same should they start building motor cycle engines. The inlet valves, I should say, will be the most difficult problem to solve, for the motor cycle engine would have to run at ever varying speeds, whereas in the aeroplane model it is practically always running at one speed, and that the highest attainable.

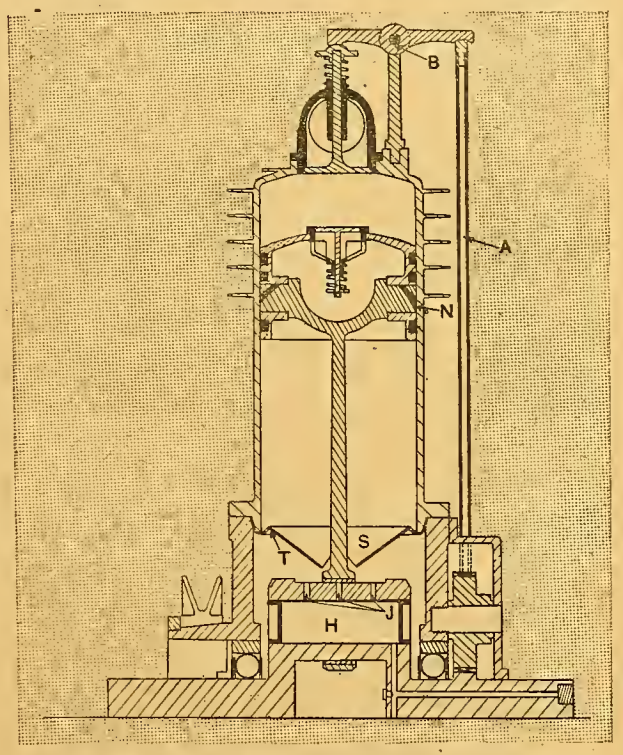

Fig. 4.—Suggested methods of balancing the exhaust valves and lubricating a rotary cylinder engine for motor cycles. A, tappet rod; B, rocking lever; H, oil reservoir in fixed hollow crank pin; J, oilways in crank pin; N, oil lead for gudgeon pin; S, baffle plate for directing oil; T, oil gutter for lubricatiug piston.

In fig. 4 a suggested method is shown how the exhaust valves might be balanced. It is to have the rod A equal in weight to the exhaust valve and its spring. When the centrifugal force becomes sufficiently strong to take effect the rod A will try to tear itself away from the centre, and so will the exhaust valve. Now the lever B will have the weight of the rod at one end and the weight of the valve at the other at the moment the valve is lifted from its seating, so that one will balance the other, while the strength of the spring will always be practically constant, and so will always be able to close the exhaust valve.

With the inlet valves the matter is much more difficult, so I will not do more than roughly indicate how it might be arranged. One way is to have all moving portions made as light as possible, and use a comparatively strong spring, which could hold its own against the centrifugal force. But this is not very

Rotary Engines for Motor Cycles.—

satisfactory, for if it were made strong enough to act well at the highest speed it would allow the valve a very poor opening when the engine was running slowly. Perhaps some system of balance weights, like what has been suggested for the exhaust valve, would be better, but, as I have already said, some research work will be necessary at this point.

Lubrication of Rotating Cylinder Engines.

The next point is the lubrication. In the Gnome engine this is done by allowing the oil to enter the

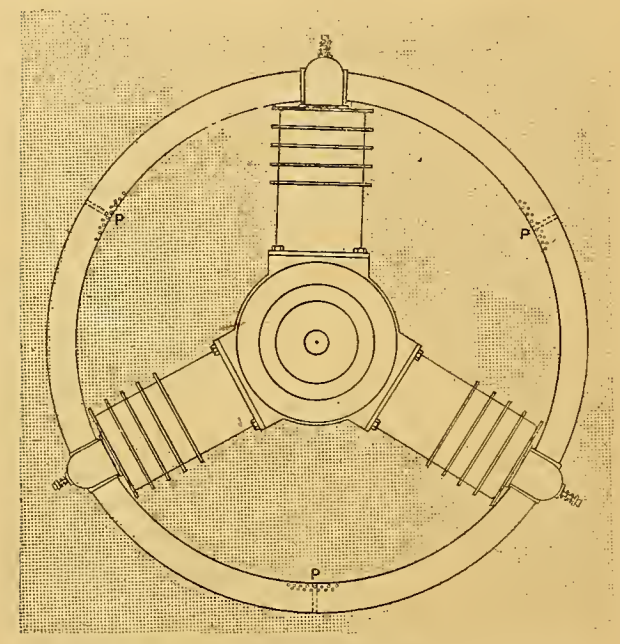

Fig. 5.—Proposed arrangement of exhaust piping on three-cylindered rotary engine. The exhaust gases are directed inwards at P, the centrifugal force keeping the oil on the outer periphery of the piping.

revolving crank chamber, where it gets flung about by the moving parts. But this method would hardly do for motor cycles, because it causes a great amount of over-lubrication when the motor is started, causing very dirty exhaust, and the oil spatters over eve thing near at hand. Some way of regulating t quantity of oil is necessary, and a suggested way shown in fig. 4. The oil is forced through t hollow crankshaft into the space in shaft H. Th chamber acts as a reservoir, and has leads J runni from it to the big ends of the connecting rods (in t sketch the leads are shown vertical, but this is only f the sake of clearness). The oil is thrown off the rods by centrifugal force on to the shields S, and t same force now causes the oil to run up these shiel into the gutter T. This gutter has a number small holes bored in it, through which the oil forced against the walls of the cylinders. The sm ends of the connecting rods take their supply throu the holes N from the cylinder walls. How th system would work in practice I do not know, b there is nothing wrong with it in theory, and it is accordance with the best principles. The idea turning the hollow crank pin into an oil reservoir not a bad one, for the crank is stationary, and the would be fed by gravity. A relief cock would, course, be necessary to run off the surplus oil.

The Question of a Silencer.

The only other point to discuss at present is t question of how to get a silencer fitted. This wou also have to collect any oil which found its way pa the exhaust valve, and might get on the machine or i rider. I think the best way would be to have a pi running between the exhaust valves, as in fig. with partitions, so that one exhaust would not inte fere with the other.

There are many other small but, nevertheles important points which would have to be gone in before this type of engine could take its place amo those suitable for motor cycles, but I think it w pay our engineers to experiment with it rather th with the two-cycle kind, as it has as many good poir and fewer bad ones, and most of its bad points c be eliminated with careful design and manufactu the success of its chief exponent, the Gnome, provi such to be the case. J. M.

ALLEGED INGENIOUS MOTOR CYCLE FRAUD.

AT the Guildhall Police Court on Monday last John Brown, 28, described as a ticket writer, who is awaiting trial upon a charge of obtaining goods by false pretences, was brought up before Mr. Alderman Johnston on an order issued by the Home Secretary in relation to a fraud and forgery alleged to have been committed by him in the City. The facts, which were practically admitted by the accused, revealed a depth of cunning and ability exercised in a somewhat original direction. In December last Brown, in the name of "G. Horne," advertised a motor cycle for sale, and received from John Edward Grace, a works foreman, of Warrington, an offer of £20. The prisoner—who had his letters sent to a confectioner's shop in Gray's Inn Road—agreed to this, and Grace sent him a post office order for £20 (in favour, of course, of "G. Horne"), payable in seven days, to allow of a trial of the machine. Grace never received the motor cycle, and consequently stopped payment of the order.

At No. 4b, Broad Street, Mr. George Horne carri on business in photographic apparatus, and December 20th he received an order signed J. E. Gra for two cameras and a lens. The value of the goo was £20, and the post office order sent by Grace "G. Horne" (the prisoner) accompanied the lett There was a request that the goods might be sent the railway station at Warrington.

Mr. Horne, believing the letter was a genuine on despatched the goods, but on presenting the post offi order he found that payment had been stopped by t remitter. It was shown that the prisoner communicate with the stationmaster at Warrington, and had t goods sent on to Euston, where he called for ther He was charged with obtaining them by false pretenc by Mr. Horne, and forging Grace's signature.

The Prisoner: I have made a full statement and se it to Scotland Yard, so that the property can recovered.

Alderman Johnston committed him for trial.

OCCASIONAL COMMENTS.

BY "IXION."

Inspection Lamps.

Acetylene dies hard, but electric lamps are in use on an increasing number of singles and on many passenger machines Their users may be grateful for a tip which facilitates inspection work at night. A couple of yards of flex with an adapter at each end is a very desirable accessory when an electric lamp is already in use. One bulb is removed from the lamp and inserted in one adapter on the flex; the other adapter is slipped into the lamp socket, and a good light is at once available for night repairs, without the need of carrying a fragile article in the toolkit. I owe this tip to a lady driver.

T.T. Machines for Touring Purposes.

I agree with practically all that "T. T. T." said in the issue of February 28th as to the general suitability of semi-racing machines for ordinary all-the-year-round roadwork, but desire to mention two drawbacks which he has omitted. One is that the frame of a T.T. machine is excessively cramped for riders of any stature surpassing the minimum, and tall men will not like the crouching attitude which is compulsory, unless the saddle is placed so far backwards that the carrier ceases to be available for a touring kit; the other is that a pair of spring forks are a desirable adjunct when the race is over. Small and medium-sized riders of some experience will be well suited with a T.T. machine if they purchase a pair of roadster forks as a spare.

Chain or Belt.

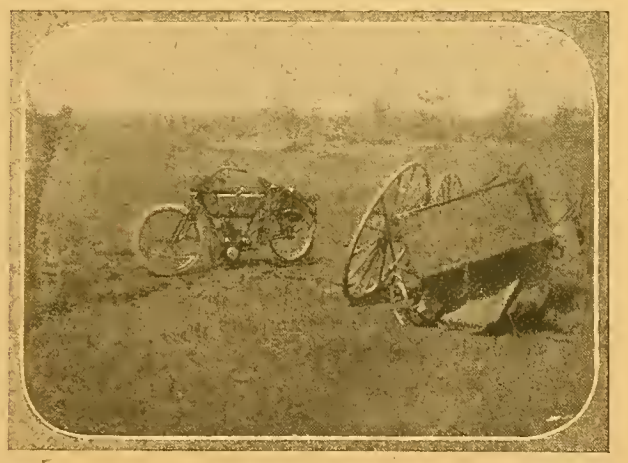
This ancient controversy is again in a position of stirabout, thanks to the partial recantation of the Hendee Company, who are now marketing in America a flat-belt 4 h.p. single, with a gear-reducing pulley, enabling very large pulleys to be fitted with a 1½in. flat belt. Readers may remember that "Transatlantic" recently stated in our columns that the greater popularity of the chain drive in the United States was chiefly ascribable to the inferior character of the motor cycle belts produced in that country, and it will be interesting to watch whether the belt secures the supremacy there as it has done over here. Further developments may be expected in the near furture in England. I hear several users of geared pulleys on lightweights have secured abnormal lives from sample belts, and that one or two designers of 3½ h.p. machines are considering experiments with large engine pulleys and reducing gears. "I hae ma doots" about the flat belt. It may be mechanical as compared with the wedging action of the V belt, which has to be "unwedged" forcibly as it quits the engine pulley, but we have yet to devise a simple and reliable fastener for the flat belt; and we must have a simple and reliable one before we can safely return to this type of transmission, even in company with a design that reduces joint troubles.

Amulree Hill and the Six Days.

I am still a trifle perturbed about the inclusion of the Kenmore side of Amulree Hill in the A.C.U. Six Days' Trial. It is true that several crack riders have made clean ascents of it with well-tuned machines under good conditions, but I doubt if a duffer would get up once in ten tries. even if his machine were in perfect order and the road and wind favourable. It is quite possible that before the competitors get so far north many engines will be a little below par, while we know how unreliable Scottish winds and weather are, even in July. I should strongly recommend amateur aspirants to put in some stiff practice on the worst and twistiest hills they can find, while riders of heavy "doddery" machines will do well to use a variable gear for this particular trial. While on the subject, I hope the route committee will vary the south-western portion a little, both in the interests of severity and scenery. The suggestion to include Cheddar Gorge is excellent.

Auxiliary Exhaust Releases.

I am naturally much interested in the adoption of the old racing idea on touring machines, by drilling the lower walls of the cylinder to afford additional paths of egress for the burnt gases. Incidentally I chortle at the growing unanimity with which the magneto is being shifted from its old muddy and back-aching position to a safer and more accessible niche, as long recommended in this column. But I have a question for the designer of the Premier which I should like to have fully answered, viz., what becomes of the oil which must be blown out through the holes drilled in his cylinder? He knows, of course, but as yet I do not, and his explanation will be interesting. From riding racing machines with the Premier holes minus the Premier cover I am aware that oceans of oil leave the cylinder *viâ* these orifices. I presume that when an outside pocket and cover are added some of the oil will drain back to the foot of the pocket, and possibly return to the cylinder; the rest will be sprayed up towards the top of the pocket (*cp.* sketch on page 168), meet the gases travelling out past the valve, and be hurled down the pipe into the silencer. I should imagine that the new engine would be a trifle extravagant in lubricating oil, and that the holes in the baffle-plates of the silencer will become sooted unless they receive more regular attention than those of a normal machine. It would be interesting to hear an authoritative description of these details of its behaviour from the men who are testing it.



"Cause and effect."
(From a photograph kindly sent by Mr. D. Skinner, jun., Queensland.)

Proposed Design for a Two-stroke Engine.

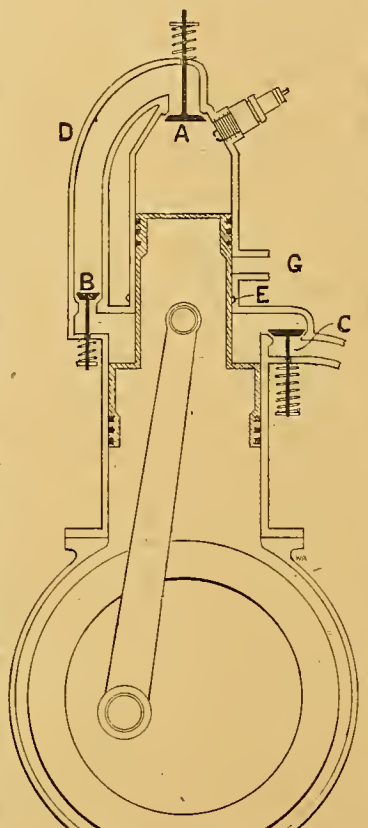
By H. W.

IN the following proposed design for a two-stroke engine the cylinder has two diameters, the lower half containing twice the cubical space of the top. The piston also is so made that when at the top of its stroke it completely fills the lower enlarged portion of the cylinder, and only leaves the compression space in the top half. There is a pipe D communicating between the lower and upper half and containing the valves A and B. The exhaust port is at G and the inlet valve at C.

The Cycle of Operations.

On the down stroke of the piston the inlet valve C is caused to open by the vacuum created, owing to the space occupied by the top half of the piston being of less diameter than the lower, and the lower cylinder is filled with mixture from the carburetter.

When the piston starts to ascend inlet valve C closes, and the mixture is forced through the valves B and A to the top portion of the cylinder *viâ* the pipe D. On the completion of the up stroke, owing to the pressure in pipe D and compression space of the engine being the same, valve A will be closed by the action of its spring. The mixture is then fired, and drives the piston down until it uncovers the exhaust port G, when part of the expended charge escapes. The pressure inside the top cylinder then falling, valve A is forced open, and the compressed mixture in the pipe D expels the remaining burnt gases. The space between the valves A and B is such that it contains sufficient mixture under compression to fill the top or working half of the cylinder and the pipe D at atmospheric pressure.



A suggested design for a two-stroke engine.
A B. Non-return valves.
C. Inlet valve.
D. Gas transfer pipe.
E. Lubricating groove.
G. Exhaust port.

During the down stroke the lower half of th cylinder has again filled as before explained, and th cycle is repeated.

The valve B serves a double purpose. It pre vents the mixture in the pipe D returnin to the lower portion of the cylinder o the down stroke, and, owing to th strength of its spring, it prevents th mixture in the lower half ascending unt the piston has covered the exhaust po G on its upstroke.

Lubrication of Connecting-rod an Pistons.

The lower part of the piston and th bearings of the connecting rod, etc depend on splash lubrication, but th top half of the cylinder has a groove ci right round it at E between the exhau port G and where it is enlarged. Th groove communicates with a pump c lubricator, which keeps it filled with oi so as to lubricate the top half of th piston.

An engine such as this should prov very flexible, as, owing to the charg being drawn in at the cool end of th cylinder and forced into the workin part, it would always receive a fu charge of gas, there being no residue c burnt gas to reduce the vacuum on th suction stroke.

Some other advantages of this desig are that there is no moving exhaust valv spring, guide, etc., and, should a back fire occur, it would be almost impossib for it to reach the carburetter, owing t there being three valves to pass, whic would all tend to close under the forc of the explosion; at the same time ther is always a free path for the gas to driv the piston down and escape through th exhaust port.

APPLICATION FOR A SPEED LIMIT AT PEMBROKE.

The Pembroke Town Council sought to enforce a ten mile speed limit under the Motor Car Act, 1903, and on the 25th ult. Mr. Marshall, an inspector under the Local Government Board, held an inquiry into the matter. The application was opposed by Mr. Deane, on behalf of the Royal Automobile Club and the Motor Union. The Mayor, Town Clerk, and several councillors supported the speed limit, on the ground that some of the streets were very narrow and crooked, and the point was emphasised that many dockyard men, by reason of their occupation, are deaf, and, therefore, need the protection of a speed limit. On the other hand expert motorists such as Colonel Mirehouse, of Angle, pointed out that the limit sought to be imposed is less than that of an ordinary bicycle, while a motor, with ordinary care, is as safe at thirty miles as at ten. Captain Mundy, dockyard superintendent, said he motored a great deal in the town and vicinity, and had many motorists who visited him, and he had never seen the slightest danger. A town councillo said he voted once for the ten mile limit, but he ha changed his mind since he bought a car and found ho perfectly the machine was under control. The inspecto took a note of the evidence, and will report in du course.

M.C.C. JARROTT CUP COMPETITION.

Mr. P. H. Trotman, a member of the club, ha offered a special prize for the best performance of rider of a lightweight machine in the London-Land End-London run at Easter. Machines with engine not exceeding 340 cc. are eligible, but there must be minimum of six such machines entered.

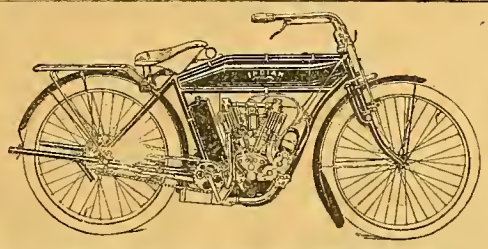
This should encourage riders of this type of machin to enter for the event, which is certainly a good tes and an enjoyable one.

Intending competitors should note that entries clos to-day week.

THE SILENT **INDIAN** MOTOCYCLE

is noted everywhere for the tremendous power it develops for its size, as has been so often proved by comparison with other machines.

When you see a machine with big cylinders, and catalogued as being of much greater power, and yet you know it cannot go as fast, under any conditions, as the INDIAN of a much smaller catalogued rating, it is certainly conclusive evidence that its alleged horse power is a misrepresentation. In other words, you do not get what you pay for.



Send for the INDIAN CATALOGUE—post free on request—it will interest you.

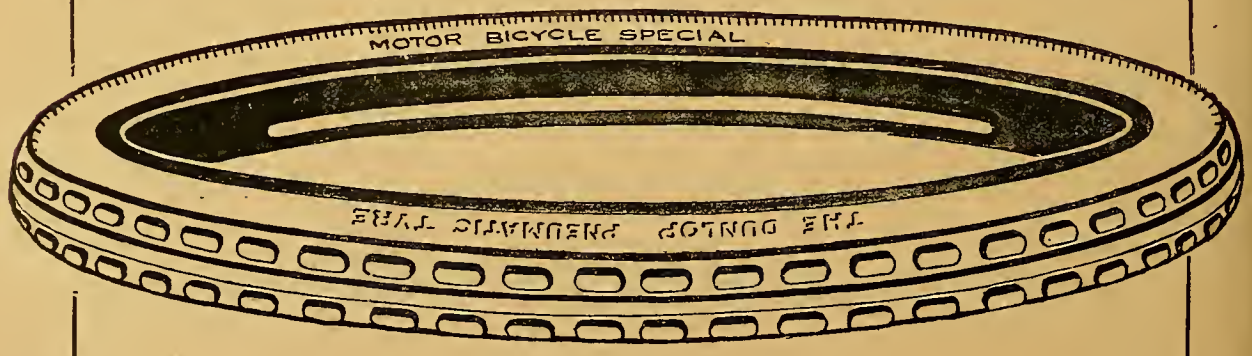
DUNLOP

RUBBER-STUDDED TYRES.

Particularly Skid-proof. Particularly Resilient. Particularly Durable.



THE DUNLOP PNEUMATIC TYRE CO., LTD., ASTON, BIRMINGHAM; ALMA STREET, COVENTRY.

Branches—London, Nottingham, Manchester, Newcastle, Bristol, Leeds, Glasgow, Dublin, Belfast.
NOTE—Tyres from which the Dunlop Co.'s private marks have been removed are not guaranteed.

Newport (Mon.) and District M.C.C.

A general meeting will be held this evening (Monday) at Central Chambers at eight o'clock.

Leicester and District M.C.C.

Another general meeting is to be held on Wednesday next at the Stag and Pheasant Hotel at 8.30 p.m. All local motor cyclists are invited.

Norwich and District M.C.C.

The first annual dinner was held under the presidency of Mr. Bernard Thorn, at the Bell Hotel, Norwich, and proved most successful. There was a good attendance.

On Easter Monday a cup presented by Mr. Thorn, the president, will be competed for in a reliability trial.

Lancashire M.C.C.

During 1910 fortnightly club runs will be held in addition to the usual competitions. A party will be formed to attend the meet of Northern motor cyclists at Richmond, Yorkshire, on Good Friday. The competitions to be held during the year will include the annual hill-climb for the Harold Eccles cup, a petrol consumption trial, and a reliability trial.

Derby Motor Cyclists to form a Club.

Arrangements have been made for a meeting to take place at the Carlton Bar, Osmaston Road, Derby, on March 9th, at eight o'clock, with a view to starting a motor cycle club for Derby and district. Motor cyclists who are interested, and cannot attend the meeting, should send a postcard to the secretary, Carlton Bar, Osmaston Road, Derby.

Southampton and District M.C.

A general meeting will be held at headquarters, The Cowherds (Golf Room), the Avenue, Southampton, on Wednesday next, 9th inst., at 8 p.m., when the following business will be transacted: Election of officers, fixing the date of the opening run, discussion of regulations for the "Oakley" Cup Competition, etc. Motorists, whether members or not, are cordially invited. The hon. sec. is Mr. H. Percy Young, Dunelm, 87, Shirley Park Road, Southampton.

Sutton Coldfield A.C.

The A.G.M. took place on the 25th ult. The balance-sheet and general report was discussed and passed as satisfactory. Seven new members were elected. The first committee meeting of 1910 took place on Friday last, when the principal competitions were decided upon. These include the annual reliability trial for silver challenge cup and gold and silver medals, petrol consumption test, and annual hill-climb at Coalport.

It is also hoped to obtain permission to hold speed trials for T.T. machines and touring mounts on a private road in the district which should prove the event of the year.

An additional hill-climb is also proposed, to be run off on a straight hill on the "knock out" principle, two riders being despatched together and the winner of each heat to compete in the semi-finals and finals.

Leeds M.C.C.

The annual dinner and presentation of prizes of the above club on the 25th ult. at headquarters was a very conspicuous success, about fifty members being present, whilst numerous delegates from the other motor cycle clubs in the district also attended. The president, Mr. Rowland Winn, was in the chair. The usual toasts and responses were made, and a first-rate musical programme followed the dinner. Dr. Norman Hughes (president of the York County M.C.C.), in the course of a neat and well-chosen speech, made special mention of the need for every motor cyclist to join a club and thus identify himself with any movement made by the different associations to improve the lot of the motor cyclist. He strongly urged the various clubs to join hands, as he assured the members that union is strength, and success can only be attained through combined effort. Other speakers included the president (Mr. Winn), Mr. J. R Kelly, Mr. A. Johnson (president Bradford M.C.C.), Mr. J. Mackay (Harrogate M.C.C.), Mr. H. Wilkinson (York County M.C.C.), Mr. H. Broadbent, Mr. J. Whittle, and Mr. F. C. Bagshaw. The hon. sec. (Mr. A. Matthews) read his report, which was enthusiastically received, and told those present that the club is in a very sound financial condition, and promised the members a real pleasant and successful season in 1910 if they would only give their officials and committee their hearty and unselfish support. The duties of toast master were admirably performed by Mr. F. O. Langton.

Evenings are drawing out! To-day's lighting up time is 6.43 p.m. (Greenwich).

A selection of questions of general interest received from readers and our replies thereto. All queries should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, E.C., and whether intended for publication or not, **must be accompanied by a stamped addressed envelope for reply.**

Curious Loss of Compression.

I purchased a second-hand 1907 Minerva recently. The compression bore the vendor's twelve stones for over a minute. I went out for a three miles trial, and when I returned I could push the machine along with the exhaust valve down. Could you explain?—H. E. A.

We can only suggest that the piston ring slots are in line, or one of the valves prevented from closing properly for some reason, or a crack has developed in the cylinder casting, which cannot be observed when cold.

A Backfire into the Carburetter.

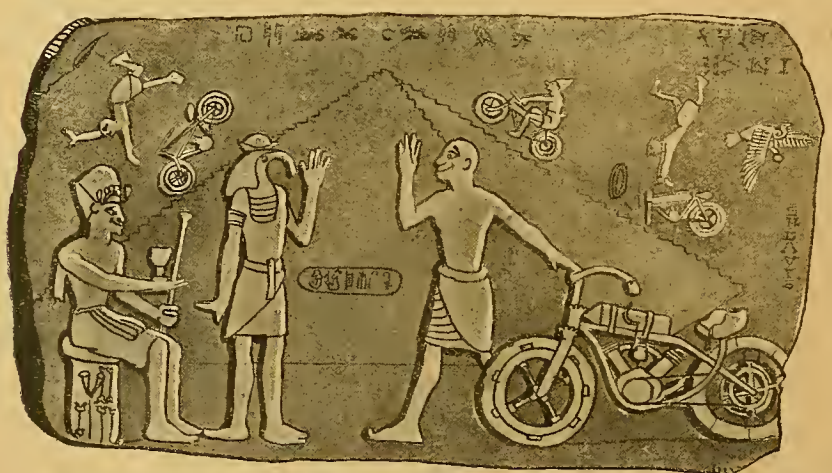
I have altered the surface carburetter of an old pattern Rex motor bicycle to a spray (B. and B.) with splendid results, but returning from a run the other day I had the carburetter catch fire, presumably through the inlet valve. I was fortunate enough to put it out before any serious damage occurred. Would it prevent such a thing occurring again if I inserted a piece of brass tube a tight fit in the inlet pipe with a piece of gauze soldered in it, or would you recommend two pieces of gauze? The inlet pipe is about 6in. in length.—E. M.

There is no doubt that two or three layers of gauze would stop the possibility of a back fire, but it would obstruct the flow of gas, *i.e.*, reduce the effective area of the induction pipe. The difficulty can probably be overcome in a more simple way by fitting a stronger inlet valve spring and reducing the opening of the valve.

Balance of Engine.

I am totally at a loss to find why I cannot average more than twenty miles per hour with my 3 h.p. machine. I have tried various adjustments of the trembler coil without success; carburetter set to combination given by the Amac Co. The engine gives full power at slow speeds, but over twenty miles per hour does not seem to give anything like the power it ought for an engine 79 × 79 mm. The engine is geared 4 to 1; if I gear lower I travel slower, as the engine only attains a certain limited speed. On going downhill the machine simply overruns the engine, and the vibration is very great. Do you think if I had the engine properly balanced I should get better results?—G. A.

The failure of the engine to attain a high rate of revolution is, we should say, due to faulty balancing of the engine or incorrect timing of the valves. You give very few details concerning the adjustments of the vital parts, but we should certainly have the balance tested by a firm of competent engineers, and also the timing. First of all, it might be advisable to communicate with the makers, as they may be able to help you.



Another reproduction of a wall carving, time of Rameses II. A competition winner is receiving a cup from Rameses in person; the god Thoth, supervisor of times, is introducing the winner. Local club members may be seen practising, and, incidentally, this is undoubted proof of the real use of the Pyramids, which has hitherto been the subject of much speculation.

Repairing an Accumulator.

I have two 12 amp. accumulators and the paste in the positive plates has fallen out. The negatives are quite good. How can I refill them, and the nature of the stuff?—A. S.

First of all you had better buy an accumulator repair outfit for taking apart the accumulator case and replacing it. The paste in the positive plate is usually composed of lead peroxide, which must be forced into the orifices of the plate by means of a roller and pressure. This operation is not at all the job for a novice to carry out, and we should strongly advise you to send the accumulator away to the makers so as to ensure the refilling being satisfactorily done, or, if you particularly wish to repair your own accumulator, a local firm of electricians would fill the plates for you.

Fitting a Two-speed Gear and Free Engine.

I have a 1906 motor cycle, 3½ h.p. single cylinder and accumulator ignition, gear 4½ to 1. It is rather bad for starting, but when once going runs splendidly, and will climb almost any hill round here without assistance from the pedals. I have also recently bought a sidecar (Chater-Lea rigid) which I wish to use with it, but up to the present have not been able to get much satisfaction from it, as the engine jibs at any hill steeper than about 1 in 18, and in addition is exceedingly difficult to start, even when the cylinder has been warmed; so much so, that I feel I should like to have it converted to a free engine and two-speed gear. Would this get over the difficulty? (1.) Is a single-cylinder engine suitable for conversion to a free engine? (2.) Are two-speed gears reliable if properly attended to?—L. B. (Heywood).

Naturally with a sidecar attached the machine has a difficulty in climbing hills without the aid of a two-speed gear, especially if you are using a 4½ to 1 gear with the sidecar attachment. The starting difficulty can probably be overcome by reducing the main air inlet. This is usually necessary during cold weather, and if the carburetter is a Longuemare it is better to fit a smaller air funnel. A two-speed gear and free engine will facilitate starting of the vehicle, but the engine itself will be no easier to start. (1.) Yes, a single-cylinder is suitable for conversion. (2.) Yes.

Heated Crank Case

Can you tell me why the crank case of my 3½ h.p. single-cylinder magneto motor cycle gets so hot that I cannot hold my hand on it? The compression seems all right when the engine is hot. I have asked several riders for the probable cause, but they do not seem to understand it. The crank case gets hot almost as soon as the cylinder itself.—T. L. W.

You do not state if the running of your engine is in any way affected by the crank case getting hot. Personally, we should be inclined to think that the crank case merely gets hot through the heat being conducted from the cylinder, but if the piston rings are at all worn this will be quite sufficient to account for the trouble.

Increasing the Comfort of Riding.

I have suffered from vibration in the past, and although I have had spring forks fitted to my machine it makes very little difference to the vibration from the handles, they seem too stiff. What is the remedy, and is a bucket seat free from vibration?—G.L.

Probably you ride with the tyres pumped up too hard. If you use long springy handle-bars, and the springs of the front fork are properly proportioned to your weight, this is all that can be done to the forepart of the machine. At the rear end, fit one of the new pattern spring saddles of large size, and if more comfort is desired, use a spring seat-pillar or shock absorbing device, such as are advertised extensively. A bucket seat is very comfortable, but it is not so easy to mount and dismount with one of these on a motor bicycle

Weather-proofing a Motor Cycle.

Re the Wilkinson T.A.C.: (1.) Would it be possible to enclose the engine in a bonnet, and have a fan at the farther end (rear), worked from engine-shaft, to draw air in from front and expel it behind? (2.) Would one have to put carburetter outside of bonnet or not? (N.B.—The carburetter is fixed behind engine, near cylinder.) Also how would this affect carburation? I understand that the carburetter needs the heat from cylinders to facilitate vaporisation, but as fan would draw hot air from cylinders past it, I take it that this would be sufficient for vaporisation. Also as to air for mixture, the carburetter would get a good supply by this means of a forced draught. I am making this enquiry with a view to enclosing front part of machine altogether to form a dashboard and wind screen. If once the cooling trouble were overcome, I could totally enclose machine, making it dust, rain, and mud-proof, thus adding extra protection to rider. (3.) At what speed would the fan have to run in relation to engine or flywheel speed?—R. H. G.

(1.) The question of fitting a bonnet or cover over the engine will be answered best by the makers. Doubtless if a bonnet be fitted a fan will be required to keep the engine cool. In its finished state the machine is provided with wind scoops to assist the cooling. (2.) The best plan will be to leave the carburetter where it is. There is no reason why it should not work well here. The makers generally know best in these respects. (3.) If the makers advise you to fit a fan, let it run about twice the engine speed.

READERS' REPLIES.

A Loss of Power.

In reading *The Motor Cycle* of February 14th, I see your answer to "P. H.'s" question. Might not a clogged silencer be the cause?—G. L. V. BAKER.

Repairing Leaky Tanks.

In reply to your enquirer, "H. C. A.," as to the best way to repair a leaky tank, perhaps my experience may help him. Halfway up Llanberis Pass I found the petrol in my tricar tank leaking very badly, the petrol cock having come unsoldered. In motoring it is not a case of what is the correct thing for a repair, but what have you got with you that will do. Among what my non-motoring friends call my "rubbish heap" I found about 12in. of light rubber tubing. In this I threaded, with the help of a hairpin, a piece of tape, and wrapped it tightly round the petrol cock. It made a perfect joint, so perfect that I was loth to remove it, which I did, however, after over three months. I found the rubber had practically formed a solid mass with the petrol cock and the tank. I hope the tip will be of service to others in a similar plight. By the way, I have got a grumble against *The Motor Cycle*. It should be published on a Saturday. I come home on Monday determined to do some work, take the cylinder off, and remove the carbon deposit, grind in the valves, etc., but the first thing that catches my eye is the "blue cover." Result—No work done till I have read it from cover to cover. Now, if it were published on Saturday, I should have all Sunday to read it. There always is a fly in the amber.—A. F. P.

"H. C. A.'s" enquiry in a recent issue in regard to a leak at the junction of the petrol cock with the tank, and your comment on the question of soldering, reminds me of the many occasions on which I have found Tinol a boon and a blessing. Some months ago I purchased a small tin of this material and one of the pocket blow lamps supplied with it, and I have often wondered the makers have not given it more publicity among motor cyclists. Little troubles constantly crop up, as every motorist knows, which an expert with solder can readily put right. The difficulty is the manipulation of the solder, whereas with Tinol I find that practically every soldering job is well within my capacity as a "very amateur" mechanic.—ALLEN FRANCKLIN.

A four-cylinder Wilkinson T.A.C. undergoing a private test on Brooklands Track. The acceleration powers of this machine greatly impress onlookers.

A PUZZLE OR A POSER?

By "IXION."

I WONDER how many readers have ever laid the palm of their hands against the extra air holes of the carburetter with the engine running fairly fast either on the stand or on the road. Of those who have done so I wonder how many have withdrawn their hand and found it bone dry, and, if so, by what methods they obviated the blowing back of a spray of wet petrol, which is almost universally found at this point on a motor cycle. For some time past I have been keenly interested in this phenomenon, and should be more interested if I could discover a machine on which it does not occur, and learn how it has been obviated, for after applying this rough and ready test to several hundred machines at different times, I have yet to find a single instance in which no petrol spray at all was blown back.

A.O.I.V. Engines the Worst Sinners.

The amount and wetness of the spray varies. On a rare machine here and there (generally with an m.o.i.v. engine) it is scarcely perceptible. On the majority, and especially with a.o.i.v. engines, it is very marked indeed. At a rough guess I should estimate that in many instances the spray is so constant and so wet as to account for a quarter of every gallon of petrol that is fed through the carburetter, *i.e.*, twenty-five per cent., and that in the best instances tested it would account for between five and ten per cent. at least of the total consumption. I am consumed with curiosity to know whether the machines which in obscure consumption trials register two hundred miles or so per gallon of petrol are devoid of this spraying or not, for up to date I have never had the opportunity of making this particular test. Here is a chance to create new records.

The Motion of the Gases.

I am no technical expert—prolonged road experience with many breeds of motor is my sole standing as a publicist—and consequently I am rather timid about opening what I hope may be a very useful and interesting discussion on this rather novel point. One thing is obvious. Most riders probably imagine that any motion existing in the inlet pipe is invariably in one direction, *i.e.*, away from the carburetter and towards the inlet valve. But wherever this spraying exists there is also another motion away from the inlet valve towards the carburetter. From the frequency of my tests this backward motion is all but universal. A second point is also tolerably obvious. This motion is practically constant. Whenever I have felt the spray it has seemed to be all but uninterrupted—as constant as the spraying of a watering can.

We know that when a single-cylinder engine is running at 1,000 r.p.m. five hundred charges of gas rush from the carburetter towards the inlet valve in each period of sixty seconds. It follows that within these five hundred forward rushes are sandwiched nearly as many backward rushes; otherwise the spraying sensation could not be constant. I have very little hesitation in saying that a backward rush immediately succeeds every forward rush, and that the backward rush is caused by the shutting of the inlet valve. Gas is travelling enginewards at high velocity when the inlet valve is open. There is nothing to arrest it for a fraction of a second after the inlet valve has shut. Then the rushing gases in the van collide with the shut valve; those in the middle of the pipe butt up against those which are crowded round the shut valve, bounce off, and are knocked roughly backwards out through the extra air orifices. It is easy to reckon that twenty-five per cent., anyway, of the atomised petrol may be wasted here. If the blow-back were as powerful as the drag of the piston when the valve is open, fifty per cent. would be wasted without allowing for the inlet valve being shut three times longer than it is open; but there is a good deal of friction in this sudden reversal of motion, and twenty-five per cent. is possibly as much as is ever wasted by this cause acting singly. Well, my puzzle, or poser, for readers is whether it is possible to stop this wastage, and, if so, how?

The Automatic Air Valve.

I have often noticed in car work that the fitting of a very crude type of automatic inlet valve, self-closing by a light spring, enormously reduces petrol consumption. It is generally supposed that the automatic valve reduces consumption by simply proportioning the feed of air more accurately than can be done by hand. I have always doubted that explanation in view of the clumsiness and inertia of the valves so often used. But the automatic air valve has a marked effect on the phenomenon now under consideration. The first backward rush shuts it, and shuts it tight. The backward rushing gas cannot escape, and for a millionth of a second or so is kept bumping to and fro in a closed chamber. By turning corners and so forth it could no doubt discover a fresh means of egress, *e.g.*, if it turned down through the spraying chamber and out through the bottom air orifices, at which very often a similar spray of less volume may be detected. Here a similar automatic air valve acting as a non-return valve upon the backward spray might be situated. No doubt some ingenuity would be required to design a carburetter provided with non-return valves at all air inlets, for if made as crudely as I have described it would give very rich mixtures at low speeds; but I am inclined to speculate that a device of this sort might be evolved which would show far more economical consumption than anything in use on motor cycles at the present time. The automatic air valve is almost unknown on motor cycle carburetters to-day; this spraying back is almost

A Puzzle or a Poser?

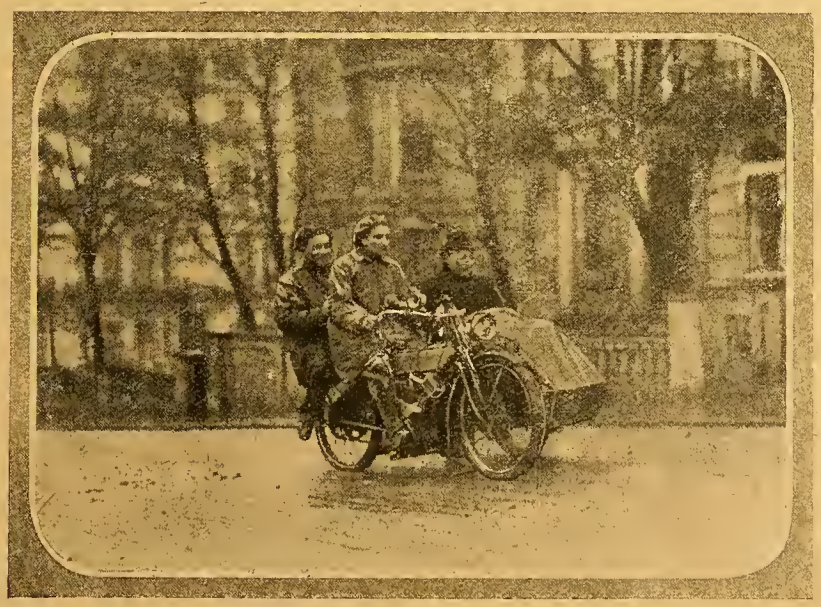
universal, and the mere presence of the spray points to a failure to get homogeneous, well-atomised mixture. The abolition of all waste and the securing of better atomisation and mixing may lead to efficiency as yet undreamt of. Extra complication may be imported. For instance, I fancy two jets with separate air valves of varying spring tension would be requisite, whatever else happens, but complications, if well made, are not radically and necessarily bad.

Mr. Mervyn O'Gorman always used to say we should all come to a forced feed of the mixture by a special pump some day, and rumour has it that some of the recent eighty-mile-an-hour bats by small car chassis on Brooklands are not innocent of forced feed. But forced feed *per se* might only accentuate what I call "spray wastage." It will all depend on strength and application of the pumping force behind the ingoing gases. The gas will continue to bounce back when the inlet valve shuts. If the pumping force is strong enough it will damp the bounce and stop the spraying; if the pumping force is not strong enough the reversal of motion will be all the stronger, and the spray wastage more pronounced. At any rate, it will be a year or two at least before forced feed can become standard on touring motor cycles, and in the meantime it seems to me that there is a good opening for a motor cycle carburetter fitted with baffles and non-return valves to trap this backward rush and obviate the present grievous waste of petrol by spraying out at the air holes.

A lightweight two-speed P. and M. climbing a 1 in 10 grade with an extra passenger on the carrier. (See below.)

A TEST OF CLIMBING ABILITIES.

THE wonderful hill-climbing abilities of the P. and M. two-speed chain-driven motor bicycle were again exemplified in a recent test on St. John's Hill, Notting Hill, W. It so happened that the day selected for the test proved wet, thus rendering hill-climbing far more difficult. A great many readers ask us from time to time what gradient a good 3½ h.p. two-speed machine will climb with a sidecar attachment and passenger, and we cannot do better than refer them to the test of the Phelon and Moore herein described, for, although it is not recommended that the machine should be burdened with the weight of an additional or third passenger seated on the carrier, it just shows what can be done with a moderate-powered machine, provided it is fitted with an efficient change speed gear. To revert to the test, St. John's Hill includes a stretch with a certified gradient of 1 in 10, although the photographs make it appear much less severe. It was pouring with rain at the time of the trial, consequently the roads were extremely heavy, yet the 3½ h.p. 82 by 88 mm. model carried three people up the hill—one in the saddle, another in the sidecar, and the third seated on the carrier—their combined weight being 31 stones. Nor was there any hesitancy on the part of the engine to perform its difficult task.

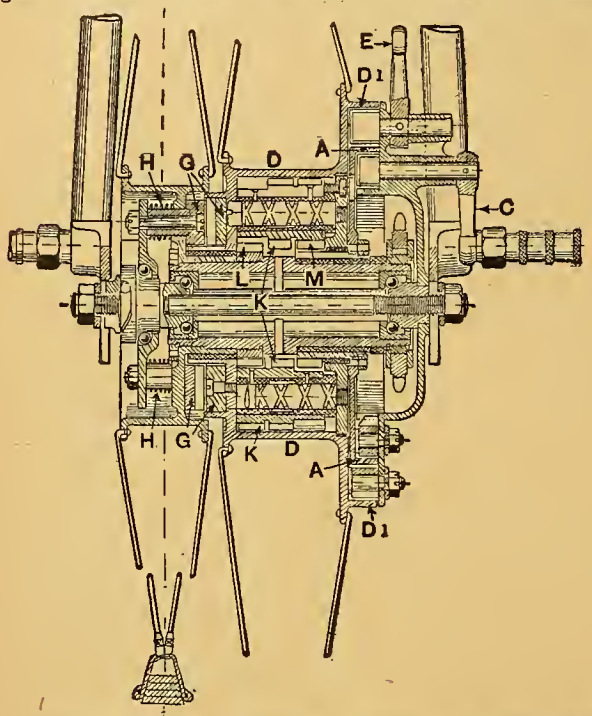


A real test! A 3½ h.p. P. and M. climbing St. John's Hill, Notting Hill, W., with three passengers.

Next the lightweight model was brought out to show its paces, and with an extra passenger on the carrier, making a total human freight of 20 st., the baby P. and M., with its 66 by 76 mm. engine rated at 2½ h.p., sailed to the summit unaided, on the low gear of course. We are asked to emphasise the fact that both machines were standard models, fitted with standard gears of 5 and 9 to 1.

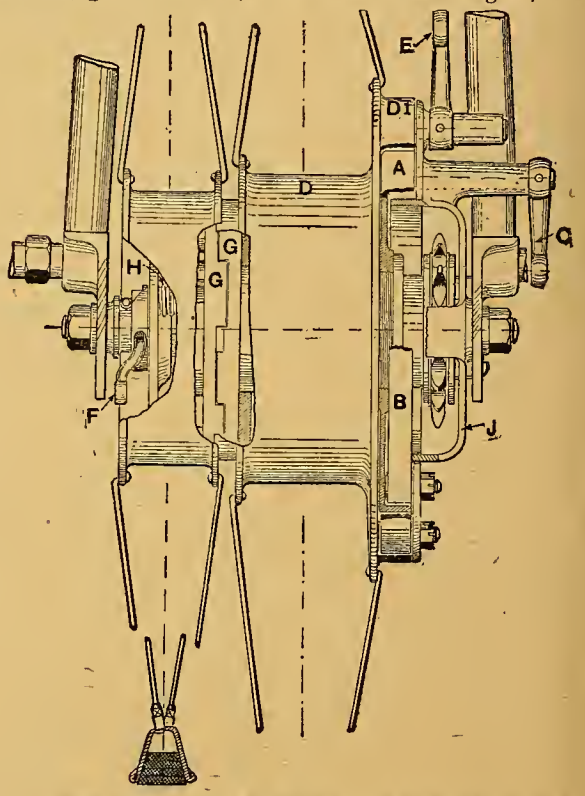
THE V.S. TWO-SPEED HUB GEAR.

AT the present time, when two-speed gears are increasing in popularity, a brief reference to the excellent V.S. two-speed gear may be interesting to our readers. The V.S. motor cycle, which under another name was so popular in the motor cycle world since its introduction into this country some six years ago, has been fitted with a two-speed gear for some time. The number of these machines



Sectional view of the V.S. Two-speed Hub Gear. This gear enables the engine to be started by the pedals with the back wheel resting on the ground. A, Brake drum for engaging low gear; B, brake band; C, lever operating low gear brake; D, hub shell; D1, extension of hub shell for ordinary brake drum; E, lever for ordinary brake; F, lever for operating free engine and engaging top speed; G, dog clutch; H, clutch disengaging spring; K, pinion gears; L, large fixed gear-wheel on hub; M, large loose gear-wheel on hub.

in use has not been great, but those that have been in use have given the greatest satisfaction to their owners. In company with many other firms who introduce a really useful innovation, the V.S. Company has had some difficulty in delivery, but now this difficulty has been totally overcome, the two-speed V.S. motor bicycles are likely to be exceedingly popular for side-car work. A proof of the reliability of the gear is its excellent behaviour in the End-to-end sidecar records. One of the chief advantages of the device is that, when it is in the free engine position, the engine can be conveniently started with the aid of the pedals with the road wheel at rest on the ground. It is interesting to note that, in the control of the gear, rods

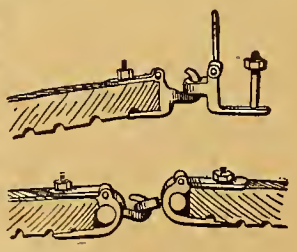


Part sectional view of the V.S. Hub Gear. The letters are referred to in the inscription under the first illustration.

and not wires are employed. On referring to the illustrations it will be seen that the gear is of the ordinary epicyclic pattern, fitted with parallel pinions. The engagement of the low gear is effected by applying the brake band B, which is applied by means of the lever C. The engagement of the top speed is by means of dog clutches.

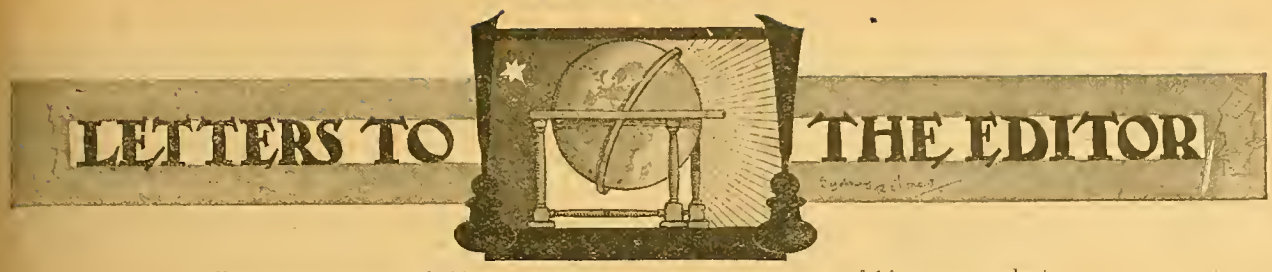
THE "GRIP" BELT FASTENER.

The patent belt fastener illustrated in the accompanying sketch has been designed to minimise the strain on fastener bolt and the hole in the belt. The bolts are rigidly attached to the bottom jaws of the fastener, and the top jaws being hinged, they can be forced down on the top of the belt by screwing up the nuts. This forcing down of the hinged jaws causes them to grip the belt and relieves the bolts of some of the strain. It is made by Mr. H. J. Smith, 60, Helena Road, Dereham Road, Norwich.



THE MOTOR CYCLE AND THE CAMERA.

Those of our readers who are not yet amateur photographers ought to read the "Bumper Number" of *Photography and Focus*, which will be on sale to-morrow (Tuesday), as its many pages are given up to a demonstration of the charms of photography as a hobby, the simplicity of modern processes, and the very little expenditure that is necessary, even when one is a hard-working amateur. A feature of the issue is the large number of very beautiful photographs by those who are quite beginners, reproduced in colour on art paper. "Photography and Touring," "Large Pictures with Small Cameras," "Cycle and Camera," "Photography at Night," and "Roll Film Photography" are a few of the subjects dealt with in what is an enormous pennyworth.



The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, E.C., and should be accompanied by the writer's full name and address.

Obtaining Particular Brands of Oil when Touring.

[4610.]—We notice in your issue of February 21st that Dr. Burrow mentions how difficult he found it to obtain standard makes of goods, such as Price's oils, when touring. We might mention that this has occurred with several of our customers, and they have got over it by opening a deposit account with us, which enables them to telephone or telegraph to us from wherever they may happen to be, when we immediately send off the goods by the next passenger train. This system has been found to be of very great convenience to many customers, and this is our excuse for troubling you with this letter. A. W. GAMAGE, LTD.

Steering of Sidecars.

[4612.]—Is Mr. J. H. Lester's theory [4609] of Mr. steering of sidecar in *The Motor Cycle* of February 14th.

As I am about to fit a sidecar to my present machine, I should esteem it a favour if you would ask Mr. Porter the distance between his motor cycle wheels. R. JONES.

[The above letter has been submitted to Mr. Porter, whose reply is given hereunder.—ED.]

"Motor cycle wheels from centre to centre are 4ft. 10⅜in. It is important that the motor cycle should stand up perfectly vertical beside the sidecar when on a perfectly level floor."—HERBERT PORTER.

[4612.]—Is Mr. J. H. Lester's theory [4609] of Mr. Herbert Porter's difficulty in sidecar steering consistent with the latter gentleman's practical remedy?

Mr. Porter suggests setting the sidecar wheel inwards. This would mean that the sidecar wheel turns round a point much nearer the front than shown in Mr. Lester's diagram. Incidentally, I do not experience the difficulty in steering that is so much discussed. I may say my sidecar is of the rigid type, and the axle is in line with the rear bicycle axle (nearly). I have put motor cyclists in my saddle who have never steered a sidecar before, and they have gone straight away with no difficulty. My wife even, without any more tuition than I gave her in the sidecar has steered me.

Sidecarists should remember that the inside wheels of any vehicle rounding a curve at speed tend to rise. As an active sidecarist of some years' experience (though limited), I should like to recommend others in general, and Dr. Vincent Burrow in particular (in retort to his complaint on page 162), to tyres made by Messrs. W. and A. Bates, of Leicester. They are no-trouble tyres indeed. My rear wheel is shod with one of theirs put on early in 1907, since retreaded with a R.O.M. non-skid; my front and side tyres are Bates's Heavy, 26 × 2½, and are as put on in 1907, and used almost daily in my work. B. RICHARDSON BILLINGS.

American Records.

[4613.]—"Another Colonial" has evidently made a grave error in the selection of his *nom-de-plume*. Surely he should have signed himself "American" right away and been done with it. He asks if I have ever heard of Peary. I have, and, like most Britishers, admire him immensely. I grant that there is no direct connection "between Dr. Cook and the motor cycle," the point at issue being the methods of making and claiming records. There is little use of twitting certain British explorers because they did not reach the Pole. *They never claimed to have reached it.*

In short, "Another Colonial" would do well to remember that British sport and records are essentially clean and honest, and are universally accepted as such, and that doping of racehorses, sprinters, etc., common in America, is looked on with disfavour by British sportsmen. COLONIAL.

[4614.]—As a Britisher I must confess to a feeling of shame when I read of the unworthy and unsportsmanlike attitude taken up by various Englishmen in your correspondence columns regarding American records. When the Indian machine was first introduced into England my greatest wish was that it would not be long before it would bow down to the superiority of British productions. But when I read letters such as have appeared in *The Motor Cycle*, I admit that it makes me long for the day when America will sweep the board in every British competition and thus lower the arrogant pride of the average Englishman. I sincerely hope there will be no more letters published belittling American records, as they reflect discredit upon the British motor cyclist as a sportsman.

FAIR PLAY.

[We do not understand why "Fair Play" should ask for no more letters on this subject to be published. It is our custom to give both sides a hearing.—ED.]

Winter Riding.

[4615.]—I hope Mr. Warburton is not going to disappoint us about further experiences with sash-cord as a non-slipping device. If a simple thing like this will enable me to ride on muddy roads without constant haunting fear of coming a sudden cropper, I for one shall be very grateful for the tip. But I am lazy, and should prefer that Mr. Warburton should make the experiment himself first, and let us know. With somewhat worn rubber-studded covers I dare not go out on muddy or greasy roads on a 3½ h.p. machine.

I hope, when we hear from Mr. Warburton again, he will let us know how far he could go on sash-cord (on mud, not ice) without wearing it through. NERVOUS RIDER.

Motor Cycle Taxation.

[4616.]—"Road Surveyor's" article discloses an unsatisfactory state of things in Scotland. It seems to me there are three road users the Chancellor might have taxed instead of raising the already high licence on motor cycles. 1st, traction engines in Scotland; 2nd, horse carriages in Ireland; 3rd, saddle horses in the whole of the kingdom. I need give no reason for taxing the two first named. I think it will be admitted by all fair-minded people that saddle-horses kept and used solely for pleasure, sport, and show, are just as much a luxury as the poor man's motor cycle.

To put it plainly, if I could afford to ride for pleasure on a horse worth forty guineas I should be exempt from taxation, instead of which I am to be hit from three or four sides to the extent of over £2 (a moderate estimate) a year for riding a motor cycle worth £8, or nearly three times as much as the owner of a trap or governess car to carry four or five persons, and as much as the gentleman's carriage and pair.

It will be argued the saddle horse is costly to keep. Then the man owning one can better afford than the motorist to pay something for the rights he enjoys on the roads. I have unsuccessfully urged this view on the local M.P. He did not agree, but could not deny the luxury question, and admitted it was a good suggestion for Mr. Lloyd George. If motor cyclists would approach their Parliamentary representatives possibly this plunder might be stayed, but I am afraid motorists are regarded as fair game to be bled. I should think that a guinea tax on saddle horses and hunters, together with the usual licence on the other two road destroyers at present exempt, would nett a good sum, and also give them a chance to pay their fair share for the roads they help to wear out and pollute. A. A.

Lightweights v. Heavyweights.

[4617.]—In reply to Mr. Marshall Thomas's letter in your journal of February 14th, I shall be most interested to see if he and his friend riding a 3½ h.p. Triumph and Rex machine respectively can climb Main-Porth hill mentioned in my letter to you of a previous date.

If Mr. Thomas cares to communicate with me through your paper, an appointment can no doubt be arranged. Incidentally I might mention that I know of a machine of the lightweight type fitted with a variable gear which can go up the above hill on the low speed without pedal assistance. It is a 2¼ h.p. 1910 model. Both the owner and myself have been up on it. It would certainly be instructive to see what a heavyweight can do. G. E. CASE MORRIS.

[4618.]—Having taken a particular interest in the controversy now raging in your "Letters to Editor" column *re* "Lightweights *versus* Heavyweights," I thought I could not let it pass without giving a word in favour of the heavyweight. With lightweights I have no experience.

Enclosed is a photograph of my machine, which was built locally by Mr. J. H. Green, 186, Derby Street, Bolton. The engine is a 3½ h.p. Minerva, Chater-Lea fittings, and a Powell two-speed free engine hub. The engine starts by a push of the pedal.

I am in the assurance business, and I use the machine for collecting every day. I might tell "Rus-in-Urbe" that on Mondays I have ninety calls, and fully sixty per cent. of those are certainly not more than three hundred yards apart.

The writer of the accompanying letter on his 3½ Chater-Lea Minerva.

I might also say I am not exactly a Sandow, inasmuch as eighteen months ago I had an accident at Gloucester, which laid me up for nine weeks.

The machine has been used for this collecting business by me every day—hail, snow, or blow—since last August up to a fortnight ago, when I took the engine down for overhauling purposes. Previous to using the motor cycle for this work I used a push-cycle, and from a six months' experience of using the motor for same work "they can take all the push-cycles to a desert island for what I care."

I think that, with all due respect to the gallant little lightweight, I can say that, given a good free engine clutch and two-speed gear (starting to be operated by pedal)—and the Powell hub I have found to be absolutely A1—there is nothing to touch a heavyweight for everyday use.

I may say my machine complete weighs 210 lbs., but, thanks to free engine clutch, it is as easy as a pedal cycle to manage. PAINLESS.

Lubrication.

[4619.]—I always find detailed experiences of riders over some thousands of miles most interesting and valuable reading. Makers' instructions concerning the above, for instance, cannot always be taken as gospel. The following are a few examples.

It is invariably stated, I think, that three pumps of oil should be put into the crankcase after cleaning out with paraffin. In my case there is quite a quantity of smoke when this is done, which never occurs at other times, yet my engine is always properly lubricated. There have been cases of plugs misfiring through this cause. I consider two to two-and-a-half pumps sufficient.

When oiling magneto, if makers' instructions are followed oil continually works into contact breaker, often getting upon platinum points and causing trouble. In my case three or four drops of ordinary cycle oil are put into each lubricating well of magneto every 200 miles, and after 4,200 miles with present mount I have not found any undue wear.

A certain variable gear which I have had fitted to my machine requires the boss of the pulley to be lubricated with grease, and the makers stated that it must be "well packed" with it. But when this is done the grease flies out when the machine is running on the road, and gets upon one's trousers. The safest plan, from the point of view of cleanliness, is that when the pulley appears to be filled up with grease, some should be extracted by reversing the direction of the plunger of the grease injector.

Why cannot British firms fit an "inspection window" in the bottom of the crankcase? This, in conjunction with an automatic lubricator, would practically dispense with a hand pump at all for any ordinary riding, as one could always tell the exact level of oil in the crank case with no trouble at all, by looking through the window a few minutes after the engine has stopped running to allow the oil to "settle." I have been told by a user that it is not a fact that the lubricator stops working in frosty or cold weather, but, of course, cannot assert this from personal knowledge. OILE.

Checking in Reliability Trials.

[4620.]—I am obliged to Mr. Scriven for his explanation of the point raised by me in connection with his article.

Successful as this system of checking appears to have been in trials organised by the Bradford M.C.C. it does not convince me that the times as taken in this way can be absolutely accurate and therefore irreproachable, and until we get such a system there is bound to be "checking grumbles" amongst the competitors. Now I do not wish to occupy any more space in *The Motor Cycle* with regard to this question, and I accept Mr. Scriven's statement that the competitors who rode under these rules are satisfied. After all, if they are all satisfied, what else matters.

Like Mr. Scriven, I also have had some experience at competing as well as organising, and must say that I am not, and never have been, satisfied with the usually adopted system of timing, and shall not fail to put the Bradford M.C.C. method into operation at the first opportunity. If I find it works satisfactorily I shall be under an obligation to Mr. Scriven for the trouble he has taken to explain it.

I do not think I have ever had the pleasure of meeting Mr. Scriven, and my name will therefore not be known to him, but I append it and hope we shall "remove this grievance" during 1910

A. E. DENDY, Hon. Trials Sec., West Essex A.C.

The Motor Cycle in the United States.

[4621.]—I find *The Motor Cycle* of the greatest interest. Several of your recent articles relating to American machines convey a rather wrong impression, however. One interview in particular, published January 3rd, criticises our motor cycles very harshly, and, I think, unfairly. The reply that Mr. Ovington made to this article I believe to be a very excellent one, but I desire to add one or two points in regard to frame lines and belts. The American Motor Co., with which I am connected, and which is one of the largest exclusive motor cycle manufacturing companies in the United States, has used the straight frame construction since 1903. During the last four years we have used an American belt, viz., the Barnes mineral tanned, flat, and 1¾in. wide. I have known many of these belts that were used over 12,000 miles and were still in excellent condition. We used last year a number of their leather V-belts which proved highly satisfactory, though not so durable as the flat. I would also like to call your attention to the fact that the handle-bar control by twisting grips which is making friends abroad originated here.

In consequence of the fact that we have never done any racing our machine is probably unknown to you, as our policy has always been to make a strong serviceable road machine for business and pleasure riding.

New York. GEO. P. JENKINS.

[4622.]—I have read with considerable interest your issue of February 7th, and wish to reply to your editorial footnote to the letter headed "The Motor Cycle in the United States," by "A Disgusted Belt User."

I have owned a motor cycle for the past six years, and until 1908 had never ridden a belt-driven machine. In the spring of the latter year I bought a 7 h.p. Peugeot and had it shipped to Los Angeles, California, where I rode it until last month.

I have motored many thousand miles on the Pacific Coast roads for touring and business purposes, and have also done some track racing, all with a V-belt.

My machine came with a French leather belt, from which I could get about 1,000 miles with very careful attention. Later I replaced this with a rubber and canvas belt which only gave me a little over 400 miles. Later still I returned to the French leather belt with better success, as I found that by running it a little slack I could get more mileage. With the latter belt I had great trouble by its pulling out at the fastening as soon as it began to get old. I had to carry many pieces for insertion, and finally carried a complete extra belt for emergency, which often arose.

During the last season I was unable at times to get the French belt without sending to France, hence was compelled to return to the rubber. I tried several of American and English makes, and not one of them carried me over 500 miles. I had exactly the same trouble as is mentioned in the letter of "A Disgusted Belt User," and I must say that at times I wished for anything but a V-belt.

In crossing mountain ranges in California, where the roads are anything but good, I had my greatest trouble, never being able to get my belt "just right." It was always too tight to get started or too loose. Upon one trip from Los Angeles to San Francisco (485 miles) I used two rubber belts, and even then had trouble in finishing with the second.

It must be mentioned, however, that a 7 h.p. machine will pull out a belt much more quickly than one of lesser power. There are many belt-driven motor cycles in California of, say, 1½ to 5 h.p. on which more mileage is done than I am able to claim, but at the same time I have only heard of one which gave over 3,000. This one was a French leather belt.

Being in the rubber business myself I have naturally been able to get hold of the best rubber belts for my personal use. However, after reviewing my past experiences with a belt-driven motor cycle, I think I shall return to my original choice, "the chain." JAMES GARVEY.

Motor Cycle Touring in India.

[4623.]—I would like to make a few remarks on Mr. G. H. Wilson's article "A Week-end Trip in India," which appeared in *The Motor Cycle* of January 3rd, 1910. Mr. Wilson seems bent on impressing those not in the know with the idea that the roads in India are well nigh impassable, but let me, with the experience of twenty years in various parts of India, assure them that the main roads are quite as good as those in England and much wider. I well remember my ride from Allahabad to Cawnpore and back, a distance of 126 miles each way, on a cushion-tyred pedal bicycle in the latter part of March, 1896. The roads were perfect, and starting at 5.30 a.m. myself and a friend similarly mounted rode until 10 a.m., when we had to halt on account of the heat. We started again at 5 p.m. and rode until 9.30 p.m., by which time we had covered ninety-one miles. We easily reached Cawnpore early next morning. We were both novices, and making due allowance for the excessive heat in that part, a head wind, and a few short halts, this does not, I think, sound like bad roads.

Although I am not now far from Bombay I am not acquainted with the roads alluded to by Mr. Wilson, but the roads here are, to say the least, very fair. Possibly Mr. Wilson's trip took him over what we call jungle tracks; these are very similar to the worst of our country lanes in England. The chief drawback to motor cycle touring in India that I have yet experienced is the great distance between places at which petrol and refreshments can be obtained, and as my mount is a lightweight this affects me strongly. Ordinary repairs I am able to do myself. I should add that our return journey from Cawnpore to Allahabad was accomplished two days later in a similar manner.

Deccan, India. A.O.C.

The A.C.U. Quarterly Trials.

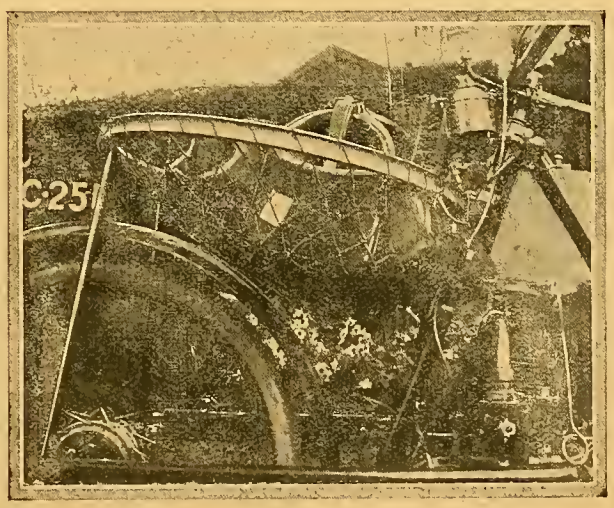
[4624.]—With your kind permission, in reference to Mr. H. H. Bowen's letter [4589], I would like to say I am quite aware that he reported his stops, but was surprised at the number of marks he was awarded.

I have read Mr. W. Cooper's letter in your issue of February 28th, and note he states his and Mr. Pratt's case clearly. He says he was the second man to start up Dashwood Hill, followed by Mr. Pratt. He says they both fell owing to their front wheels fouling a rut. I am quite willing to admit that the ashes thrown on the road were an advantage in starting, but I would point out that Mr. Pratt got forty yards from the start before he fell; therefore I fail to see how the ashes at the starting point would have prevented his fall. Mr. Cooper states that he is quite satisfied to abide by the judges' decision, and then goes on to say he does not agree with Messrs. G. Lee Evans and W. O. Bentley (Indian) being awarded non-stops.

I cannot understand any competitor saying he is satisfied when such glaring mistakes have been made, except he be one of the favoured ones. I have no wish to have the A.C.U. rules made to fit my own particular case, but would like to know that the rules would be enforced in all cases.

I have been a competitor in A.C.U. events since 1904, and I quite agree with Mr. Cooper that the object should be to assist rather than to disparage the judges, and would like to suggest, their task being a heavy one, that they accept some of the outside help so willingly offered.

I hope to compete in future A.C.U. events, and perhaps it may not be to my advantage to complain, but I do so in the interest of those competitors who wish to see fair play and no favour. ELI CLARK.



A novel form of luggage carrier attached to a Zenith Bicar in use in New Zealand. A wheel rim has been adopted, and a string bag holds all necessary touring equipment.

EXPERIENCES WANTED.

"J. S. P." (Lancs.) desires users' opinions of the Moto sacoche or 2 h.p. Moto-Rêve.

"J. S. V." (Warrington) would like readers' experiences of the Mabon clutch on a 3½ h.p. Triumph, particularly in connection with hill-climbing.

"H 3545" would be glad if readers would give him their experience of the F.N. two-speed gear with the 5-6 four-cylinder motor bicycle, or of the same machine and sidecar without the two-speed gear.

"A B. V." (Launceston) would be glad if any owner of a 3½ h.p. Minerva (1908 model) could inform him how to prevent overheating. He has tried lowering the compression without any good result. Gear 5¼ to 1. Weight of rider, 12 stones.

"E. F. E." (Ealing) would like readers' experiences with the A.C. tricar (racing model). Does it compare favourably with a motor bicycle and sidecar of equal h.p.?

"E. W." (Norfolk) would be glad to have owners' experiences of the Unito or other coupling. Also of the 3 h.p. N.S.U. motor bicycle, and L.M.C. variable pulley and free engine.

British Magnetos in the States.

Mr. F. R. Simms, chairman of the Simms Magneto Co., Ltd., is at present in New York, where the question of assembling and finishing Simms magnetos as well as their manufacture in the States will occupy his attention during the next two or three months.

Collier's Monoplane.

Motor cyclists interested in aeronautics should turn their attention to *The Aero*. Many well-known motor cyclists, such as Collier Brothers, have devoted their attention to aeroplanes. A detailed description with illustrations of Collier's monoplane will appear in this week's issue of *The Aero*, on sale to-morrow.

The De Beers Atomiser.

Some time ago there appeared a description and an account of some experiences we had with the De Beers carburetter jet. This jet, as our readers may remember, consists of a hollow cylinder containing a piston in which helical grooves are cut. The top of the cylinder is closed except for a small orifice, while the petrol entering at the bottom causes the piston to revolve and atomise the spirit in a most effective manner. The chief advantages claimed for the jet are economy, increased efficiency, and flexibility. For one month only, Petrol Economisers, Ltd., Avenue Chambers, Southampton Row, W.C., have decided to place these jets on the market at an exceedingly moderate figure to enable motor cyclists to give them a trial.

SPARKLETS

Catalogues Received.

The Wearwell Cycle Co., Wolverhampton, are devoting a certain section of their cycle catalogue, of which we have just received a copy, to motor cycle accessories which they stock.

The Moto-Rêve Co., Ltd., Acton Vale, W., send us a 1910 catalogue of the Moto-Rêve lightweight motor cycles. Including the lady's machine there are now six models of the Moto-Rêve, varying in weight from 78 to 94 lbs. Model B, the single-cylinder, is, of course, the lightest of all. Copies of this catalogue will be sent free on application to the works at the above address.

"Everything for the Motorist" was the title adopted by A. W. Gamage, Ltd., some two or three years ago for their catalogue, and we do not think a better title could possibly have been selected for the 1910 issue, which is just to hand. Practically every known accessory on the market is included in this bulky volume, which consists of 158 pages. Not only are the up-to-date articles in the way of accessories, clothing, tyres, etc., catalogued and priced, but there are innumerable fittings included which are constantly being required by motor cyclists who possess machines which are not of the very latest type. All the pages are not devoted to motor cycle goods, the catalogue being a general one embracing the pastime from a motor car and motor cycle point of view. Copies will be sent on application to A. W. Gamage, Ltd., Holborn.

A Hint.

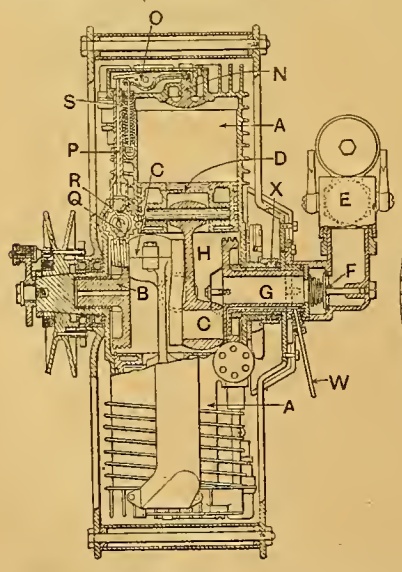
Customers unwittingly often give manufacturers a great deal of unnecessary trouble, simply because they persist in addressing letters to individual members of a firm instead of to the company. A recent instance of the trouble caused by this procedure was brought to our notice the other day. A certain motor cyclist was an intimate friend of a well-known rider employed by a firm in London. The rider in question was away in Manchester, and his friend addressed him a personal letter instructing him to send for his motor cycle from one of the London termini, enclosing the cloak room ticket. Owing to the individual to whom the letter was addressed being away, it was forwarded to him at the Manchester Show, and after three days' delay the head of the firm found out what the instructions were, and they were at once carried out. In the meantime, the customer sent a furious letter to the firm asking why his communication had not received attention. We think this instance serves to show how important it is not to address business letters to individual members of a firm.

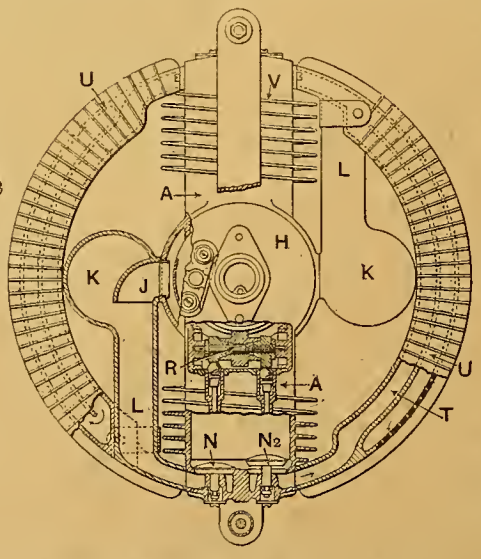
A RECENT PATENT.

By ERIC W. WALFORD F.C.I.P.A.

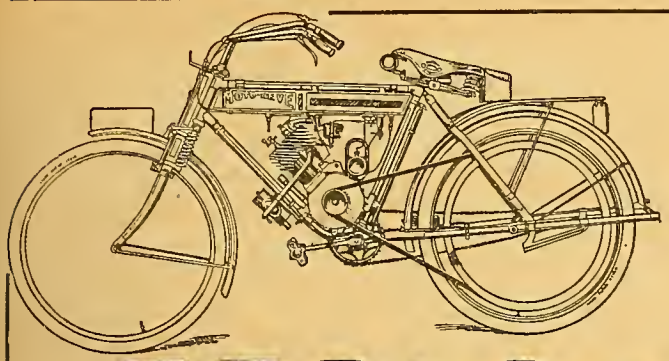
A Rotary Engine.

This engine (formerly known as the Barry) is of the Gnome type, which is being largely used on aeroplanes. In the present case there are two cylinders A diametrically opposite one another, and





these rotate around a stationary crankshaft B. The crankshaft is formed with two crank pins C, each of which is connected to one of the pistons D. The pistons consequently move inwards and outwards together at the same time as the cylinders rotate. The carburetter is shown at E, and as the pistons move outwards suction is set up, drawing the gas past the spring-loaded valve F through the hollow crankshaft at G, and into the crank chamber H. As the pistons move inwards, the gas is forced through one of the nozzles J into a storage chamber K, and from here it finds its way along the induction pipe L through the inlet valve N into the cylinder. The valves are both operated by rockers O, tappet rods P, and adjustable cams Q, these cams being mounted upon a crankshaft R rotated by spiral gearing, as shown. Each of the valves is actuated by a spring at S, which keeps it closed, but, of course, centrifugal action as soon as the engine starts is sufficient to keep each valve on its seat. Exhaust takes place through the exhaust valve N_2 entering the exhaust passage T of the silencer U. The silencer rotates with the cylinders, and is ribbed for cooling purposes, the cylinders also being provided with inclined flanges V at such an angle that the air impinges forcibly upon them, so that a maximum cooling effect is obtained. Lubricating oil is admitted by the passage W into the hollow crankshaft, and the outer portion of the shaft is provided with packing at X to maintain the crank chamber gas-tight. Of course, by employing rotary cylinders, one can dispense with the flywheels, and, as there are no reciprocating parts, the whole engine can be very easily balanced, and can be so constructed as to be practically vibrationless.—W. A. Richards and C. R. Redrup, No. 27,596, 1908.



THIS IS THE MACHINE the

MOTO-REVE

LIGHTWEIGHT

—we wish to take you for your holidays. You cannot possibly do better. The price **27** guineas, the weight 78 lbs.

PRINCIPAL POINTS.—Magneto Ignition, Druid Spring Forks, Entire Handle-bar Control, Stand, Carrier, Number Plate, Single-cylinder (60 x 85 m/m). All complete and ready for use. Send for Catalogue.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns—1d. per word, minimum 1s. Name and address must be counted. In the case of Trade Advertisements a series of thirteen insertions is charged as twelve.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor Street, E.C.), on Tuesday morning previous to the date of issue.

When possible advertisements received at Coventry on the Wednesday will be inserted.

All letters relating to advertisements should state distinctly under what heading and in what issue the announcement appeared.

CLASSIFICATION BY LOCALITY.

For the convenience of purchasers of second-hand motor cycles, the advertisements are classified into districts, as many readers like to know what machines are for sale in their immediate neighbourhood before going further afield.

Plan showing division of England into Sections.

SECTION I.
Northumberland, Cumberland, Durham, and Westmoreland.

SECTION II.
York and Lancashire.

SECTION III.
Carnarvon, Denbigh, Flint, Cheshire, Leroy, Stafford Shropshire, Montgomery, and Merioneth.

SECTION IV.
Nottingham, Lincoln, Leicester, Rutland, Northampton, Warwick.

WAUCHOPE'S, 9, SHOE LANE, FLEET ST., LONDON, E.C.

'Phone, 5777 Holborn. Telegrams: "Opificer, London."

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, 2d. will be charged for registration, and three stamped and addressed envelopes must be sent for forwarding replies. Only the number will appear in the advertisement. Replies should be addressed, "No. 000, c/o 'The Motor Cycle,' Coventry"; or if "London" is added to the address, then to the number given, c/o "The Motor Cycle," 20, Tudor Street, E.C.

DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt, and upon intimation of the arrival and acceptance of the goods, the money is forwarded less a charge of 1s. for registration. The time allowed for a decision after receipt of the goods is three days, and if no sale is effected, each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe and Sons Limited.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

We maintain the "Coronet" is the BEST DESIGNED SIDECAR on the Market.

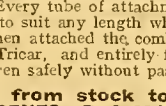
Free from Side-slip.—The "Coronet" Sidecar is attached in three places, the front down tube, bottom stay, and saddle bolt, and can be detached in three minutes. Every tube of attachment is telescopical and adjustable to suit any length wheelbase, any height or width. When attached the combination is as firm and rigid as a Tricar, and entirely free from side-slip, and can be driven safely without passenger if desired.

Delivery from stock to suit TRIUMPHS, REXES, P. & M.'s, N.S.U.'s.

Price £4 17s. 6d. Discount to trade.

CORONET ADJUSTABLE PULLEY.

12/6



The best variable speed pulley on the market. Loose flange securely held in any position by a simple yet ingenious contrivance. Gear can be altered without the aid of spanners, lock ring easily operated by hand. Buy a "Coronet" pulley and gear your machine suitable for hill-climbing.

Standard makes, such as Rexes, Triumphs, Minervas, supplied without the necessity of sending old pulley for pattern. **Discount to trade.**

"GRIPSKIN" BELTING.

Made from selected parts of hides, correct angle, perfect drive; the best leather belt on the market. Longer life than rubber.

⅝in., **10d.**; ¾in., **11d.**; ⅞in., **1/1**; 1in., **1/2.**

CAMEL

Franco-British Exhibition 1908.

3 *Grand Prix.* 8 *Gold Medals.*

As a chain is only as strong as its weakest link, a belt is only as efficient as its least considered essential.

The essential links in motor belting construction—Maximum effective pulling surface; Elimination of stretch; Tensile strength; Flexibility; Centring of core; Prevention of twisting, ends breaking, and surface cracking—when evenly considered and supported by suitable materials and experience, ensure a perfect whole.

Camel Belting, owing to its uniform wear, due to scientific construction, is offered and sold as being the nearest possible to the ideal.

Obtainable through all Agents.

THE MOTOR CYCLE SUPPLEMENT

AUXILIARY EXHAUST RELEASE.

RECOMMENDATION OF "THE MOTOR CYCLE" ADOPTED. THE QUESTION OF STARTERS.

WITH regard to the leaderette in last week's issue criticising the proposition of the Brooklands Automobile Racing Club to rule out machines fitted with drilled cylinders or auxiliary exhaust ports, we are pleased to be in a position to announce that on further consideration the rule appearing in the first sheet announcement respecting the two Easter events has been deleted. In its place the following words will appear: "Entrants must state on the entry forms whether their cycles are fitted with drilled cylinders or auxiliary exhaust ports."

Major F. Lindsay Lloyd asks us to give publicity to the above notice, and incidentally he assures us that the rule referred to was merely a condition which applied to the two Easter events for motor cycles, and to those two races only, and there was no intention of making this a permanent rule. Record attempts or international races, he points out, would always be open to machines fitted with the drilled cylinders; consequently it was unlikely that a permanent rule would be made on the subject.

Should Starters be Barred?

Major F. Lindsay Lloyd, who exhibits a commendable desire to please all, further says: "It would be interesting to know the feelings of motor cyclists on the question of starters. So far we have barred starters, acting on the advice of prominent motor cyclists, but I find that there is a growing feeling that starters should be allowed, especially for the more high-powered machines." Correspondence on this subject would be of interest and great assistance to the B.A.R.C. Of course, should starters be allowed, stringent regulations would have to be made with regard to their leaving the track as soon as the machines had started.

THE 1910 END-TO-END TRIALS.

THE rules governing the Land's End to John-o'-Groat's Six Days' Trials, July 4th to 9th, are now complete.

The route has been altered since it was last published, and the competitors, after leaving Taunton, will go through Bridgwater, Highbridge, Cross, Axbridge, up Cheddar Gorge, through Chew Stoke, Dundry Hill, to Bedminster Bridge, Bristol. From Bristol the old route is to be followed. This alteration is the outcome of a suggestion which lately appeared in the correspondence columns of *The Motor Cycle*.

The time of starting, 8 a.m., and the entrance fees remain the same as in 1908.

Bronze medals will be awarded to each rider who finishes at John-o'-Groat's before midnight on Saturday, July 9th, and who otherwise fulfils the conditions of the trial and does not obtain any other award.

Marks will be awarded in the following proportions:

Reliability	100
Brakes	50
Hill-climbing capabilities	80
Condition of machine during and after trial	100
Accessibility	20
Silencer	20
Condition of tyres at end of trial	50

The minimum time is calculated on a basis of twenty miles an hour; the maximum time eighteen miles per hour.

No repairs are to be done during the luncheon stop.

In order to discourage waiting outside controls any competitor arriving within one mile of the checking station ten minutes or more in advance of schedule time will be penalised ten marks on each occasion.

Each day's run will finish at twelve o'clock midnight. Any competitor not completing the full day's course by this time automatically retires from the trial.

A competitor may stop and make any repairs or adjustments to his machine that may be necessary during the day's run, but there must be no organised assistance. Any replacements, including tyres, must be made from parts actually carried on the machine or person of the rider.

A driver will not be admitted to the storage until thirty minutes before the official starting time, when he may clean his machine and effect any replacements or adjustments.

All important parts of the machine will be sealed, and this year tyres and belts will be branded.

On the evening of the running day when the machines arrive at their destination they must be taken direct to the storage and left in charge of the A.C.U. official by the competitor. No adjustment whatever may be made.

The luncheon stop will be one hour instead of one hour and a half as in 1908. During that period the tanks only may be filled.

From the above alterations it will be seen that the Six Days' Trial is far more strenuous than it was two years ago.

J. Scriven (Rex) and J. Adamson (Triumph) are the latest entries for the Tourist Trophy Race.

H. H. Bowen has entered his Bat-J.A.P. for the End-to-end Six Days' Trial.

A. J. Moorhouse, another of our best known motor cyclists, has joined the Indian tribe, and is on the warpath for the Tourist Trophy.

Six Days' Trials Route Fixed.

The route for the Land's End to John-o'-Groat's Six Days' Trial has now been definitely fixed, and totals about 1,006 miles.

A.C.U. Meeting.

This evening (Monday), at seven o'clock, a meeting will be held at 112, Piccadilly, W., of delegates of the clubs in the Metropolitan centre of the A.C.U.

Next Week

Accessories and equipment will be specially dealt with. The issue will make a timely appearance at this period, when motor cyclists are busy fitting out their new mounts, and others renovating and bringing up to date tried and trusty steeds.

Good News.

H.S.H. Prince Francis of Teck has kindly consented to give away the prizes on the occasion of the British Motor Cycle Racing Club's first meeting of the year, which will take place at Brooklands on the 16th inst.

Open Hill-climb.

A permit has been granted by the A.C.U. to the Herts County A.C. (Motor Cycle Section) to hold an open hill-climb at Aston Hill, Tring, on Saturday, May 7th. This will probably be the first open event of its kind during 1910.

The Motor Cycle Show at Olympia.

The necessary draft agreement is now being drawn up by the Society of Motor Manufacturers and Traders for the occupation of Olympia by the Cycle and Motor Cycle Manufacturers' and Traders' Union, Ltd., next November. We announced some weeks ago that the latter body would hold a cycle and motor cycle exhibition during that month, following the car show.

Brooklands Hill-climbing Certificates.

Major F. Lindsay Lloyd is now issuing printed certificates to manufacturers and others for all motor cycles which can climb the Brooklands Test Hill from a standing start. The fee is 2s. 6d. The certificate gives the frame and engine numbers and the gradient of the test hill.

Free Legal Advice.

From the inception of *The Motor Cycle* in 1903 hundreds of our readers have received free legal advice either by letter or through the medium of the "Questions and Replies" columns. This is a feature which has always been embodied with the replies to correspondents, an average of about two hundred of which are dealt with each week from this office. All enquiries of a legal nature are submitted to our legal adviser, and the replies are posted to readers, the only condition being a stamped addressed envelope. Only a few of those of general interest are published

M.C.C. London-Edinburgh Run.

Several entries have already been received for the London-Edinburgh run, one from so far north as Newcastle-on-Tyne and another from Cardiff; both are from members who rode in last year's event. The new route has been greatly appreciated, and no stone is being left unturned to thoroughly marshal it, thanks to Mr. Bates and other members of the Newcastle and Dis. M.C.C., and Mr. Watson, of Edinburgh. The final control, corresponding to Levenhall of previous years, will probably be at the turning where the Galashiels road enters the tram route into Edinburgh, entering between the Post Office and the North British Hotel. The new route is, incidentally, free from sharp turnings and ten-mile limits, so that in this respect at any rate the new route is an improvement.

The Inter-team Trial at Easter.

The inter-team reliability trial of the Herts County A.C. and North West London M.C.C. at Easter is already an assured success. The accommodation at one of the largest hotels in Harrogate has been taken up by members intending to take part in the tour.

A Trade Item.

Under the heading of new companies, it is announced that the Cycle and Motor Cycle Manufacturers' and Traders' Union, Ltd., has just been registered with three hundred members, each liable for £1 in the event of winding up, to take over the property and all or any of the liabilities of the Cycle and Motor Trades' Association (established in 1890), of Coventry. The subscribers are: W. G. Jenks, A. S. Hill, H. Smith, C. V. Pugh, J. Hazlewood, W. H. Fulford, and R. Burns.

Hill-climbs in N.S.W.

The Motor Cycle Club of New South Wales held a hill-climb, for motor cyclist members of the N.S.W. Cyclists' Union, at Coogee, Sydney, N.S.W., on January 22nd. Out of twenty-two entrants, ten started, racing in pairs until the final. W. W. Reynolds, on a 3½ h.p. Triumph, defeated J. Juleff (3 h.p. Lincoln Elk) in the final. S. Crouch (2 h.p. Moto-Rêve) made fastest time under 3 h.p., and W. L. Cobb (3½ h.p. Triumph) fastest for over that power.

A.C.U. Inter-club Championship.

The rules for what was first termed the "inter-club efficiency contest," but now the "inter-club championship," are now ready. We have not space to publish them in detail, but the following brief notes make clear the nature of the competition: Reliability and petrol consumption will be taken into account. Preliminary competitions will be run off in the various centres, the winning teams in each centre to meet in a final competition to be held in the Midland Counties. The contest is open to any club affiliated to the Auto Cycle Union, or officially recognised by the Motor Cycle Union of Ireland and the Scottish Cyclists' Union. Each club team will comprise six riders and machines, and each club must nominate three riders and machines as reserves. The actual competing team must consist of four single-cylinder motor cycles, and two multi-cylinder motor cycles. Passenger machines are eligible. The entry fee per team is 21s., which will be equally divided between headquarters and the centre. The distance of the final contest will be about 160 miles. For the preliminary contest, each centre will select its own course, which must not be less than 140, or more than 160 miles. Pedalling is prohibited.

Special Features

AUXILIARY EXHAUST RELEASE.
Brooklands Regulation Withdrawn.
ACROSS THE AMERICAN CONTINENT ON A MOTOR CYCLE.
ROTARY ENGINES FOR MOTOR CYCLES.

Annual General Meeting of A.C.U. Private Members.

The annual general meeting of private members of the A.C.U. was held on Wednesday. The business of the meeting was to receive nominations of councillors who should be supported at the election of the committee. The following members were recommended for election on the General Committee at the council meeting: Messrs. Brooker, Cove, Pratt, Sharp, Bischoff, Reynolds, Hart, Harding, Hall, Wells, Cooper, and Nelson.

A.C.U. Quarterly Reliability Trials.

The A.C.U. secretary, Mr. F. Straight, writes: "The letters of complaint with reference to the marks awarded in the last Quarterly Trial, which have appeared in your columns, can be divided into two classes. One series refers to Dashwood Hill, and the other to various traffic stops during the course of the trial.

"In the published report of the judges it has already been explained that, owing to the icy surface of the road at the foot of Dashwood Hill, the competitors who, according to the regulations, were stopped and instructed to restart from rest, found it practically impossible to get a foothold. The judges, exercising their discretion, thereupon instructed the remainder of the competitors to proceed up the hill without stopping. A difficulty naturally arose as to awarding marks for Dashwood. Bearing this in mind, and after careful consideration, the judges came to the conclusion that the fairest procedure to all was to allow those competitors who had made a good ascent to score marks according to the performance, whilst those who had stopped or fallen should be judged by their performance on Rectory Hill. Therefore the marks those competitors gained on Rectory were also allotted to them in respect of Dashwood. It will be seen, upon referring to the published awards, that no competitor has been given fewer marks for Dashwood than for Rectory. The other series of complaints refers to one or two riders credited with non-stops having been seen running alongside their machines. One of the regulations refers to traffic stops, which are, of course, sometimes absolutely unavoidable, in the interests of the public safety, and are therefore not counted against a non-stop performance. The Committee of the A.C.U. requested the riders in question to attend a meeting to explain the circumstances. The judges heard their statements, which were quite frank and satisfactory. They saw no good reason for cancelling the non-stop awards.

"The judges, in view of all the evidence before them, do not see any cause for further consideration of the awards as now published."

Hill-climb in Manxland.

It has been definitely decided to hold an open hill-climb in the Isle of Man on the afternoon of the day following the Tourist Trophy, namely, Friday, May 27th.

Amulree.

Latest accounts from Kenmore—the venue of the hill-climbing test in the End-to-end Trials next July—show that the district is still covered with snow, and the surface of the hills is in a very bad condition.

Upkeep of the Roads.

According to an authority, there are at the present time 2,014 different bodies in England and Wales having charge of the upkeep and maintenance of the roads. This is the cause of much overlapping, whereas if one central body had charge much unnecessary expense would be avoided.

A.C.U. Notes.

At a recent meeting of the A.C.U. committee, a number of new members were elected.

Handicappers.—Messrs. Ebblewhite and Dutton have been appointed official handicappers to the A.C.U.

Affiliation.—The Westmoreland M.C.C. has recently affiliated to the A.C.U.

Auto Cycle Legion.

Membership of the Auto Cycle Legion has now been thrown open to all motor cyclists interested and who are anxious to serve their country in time of peace or war. The subscription will be 5s., which will include affiliation to the A.C.U. The Auto Cycle Legion will be managed by an Executive Committee, one of the members of which will be an expert military authority.

A Proposal to the War Office.

A proposal is about to be laid before the Director of Military Training, providing for detachments of motor cyclists for dispatch riding, etc., in different parts of the kingdom where required by the Army Council. Each detachment will be commanded by a captain responsible to the colonel of the Motor Cycle Corps. It is suggested that the corps be administered from the War Office in the same way as the Officers Training Corps, and that funds be provided for uniforms and preliminary training by means of a capitation grant payable to the corps on account of every efficient man. It is proposed that the men be only sworn in for one year at a time, owing to the fact that the machines wear out and may not be replaced. Pay and allowance on mobilisation or manœuvres, staff rides, etc., are asked for as follows: Petrol and cycle allowance, 6s. 6d. per diem; special allowance, 4s. per diem (for board and lodging when not provided). The above are in addition to the ordinary Territorial rates of pay. The suggested uniform will be on Territorial lines, but provides for a field service cap which, when unfolded, will give some protection, and also for oilskin overalls of strong material. A few preliminary drills will be necessary for the recruit to give him confidence and a military bearing, but the preliminary training to be performed each year by a trained man in order to earn the capitation grant will probably consist partly of lectures and partly of instructional runs. Needless to say, the man who does not earn his capitation grant cannot expect to be detailed for manœuvres or staff rides. The intending recruit has therefore little of an arduous nature to go through in the matter of training, and certainly not a tithe of what the Territorial has to perform; he makes up the balance by his technical skill acquired by several years of road experience.

CLUB NEWS.

(SEE ALSO PAGE 187.)

East Sussex M.C.C.

The above club is of recent formation, and local readers desiring information should write the hon. sec., Mr. R. G. Hudson, Clifton Hotel, Eastbourne. The subscription is 5s., with an entrance fee of 1s.

Nottingham and District M.C.C.

The Alfreton and District M.C.C. has extended an invitation to members of the Nottingham club for their smoking concert at the Assembly Rooms, Alfreton, to-morrow (Tuesday), at 8 p.m. Mr. J. Elliott Littlewood presided over a committee meeting on Wednesday last, when the hon. secretary reported that Lord Henry Bentinck, M.P., and Captain J. Archibald Morrison, M.P., had accepted respectively the presidency and vice-presidency for 1910. Mr. F. W. Johnson had also consented to be a vice-president. Messrs. Littlewood, Dance, Cuthbert, and Spring were appointed to attend the inaugural meeting of the Notts Centre of the A.C.U.

British Motor Cycle Racing Club.

The events down for decision at the meeting at Brooklands on Wednesday week, the 16th inst., are: All-comers' Handicap, distance 5½ miles, start 2.30 p.m.; and One Hour T.T. Race.

Scarborough and District M.C.

The annual meeting was held at the Pavilion Hotel on the 28th ult., Mr. Ringrose being in the chair. The meeting was very well attended. The secretary (Mr. Tranmer) read the report. The club commenced the year with twenty-one members, and there were thirty-seven at the end. There is a balance in hand of £8 4s. 6d. It is proposed to hold more competitions this year.

Bath C.C. Proposed Motor Cycle Section.

This well-known and old-established club is calling a meeting of all motor cyclists residing in the district at the Castle Hotel, Bath, for Monday, March 14th, with the object of forming a motor cyclist section and enrolling new members.

The University of Birmingham M.C.

The above club has already held its opening run. Meeting at 11 a.m., the members proceeded to Stratford-on-Avon, lunch being partaken of at the Swan's Nest Hotel. After lunch the run was continued to Sunrising Hill, several members making clean ascents, notwithstanding the heavy roads. Thence to Warwick, where a halt was made, and home.

Redditch & District M.C.C.

At a well-attended meeting, held at the Unicorn Hotel last Thursday, it was decided to form a club, to be known as above. Mr. W. F. Skinner, 4, Prospect Hill, Redditch, is the hon. secretary.

FUTURE EVENTS.

Mar. 16—(Wed.) British Motor Cycle Racing Club Meeting at Brooklands.
" 25—General Meeting of Northern Motor Cycle Clubs at Richmond, Yorks
" 25-28—M.C.C. Opening Run. Easter Tour to Salisbury. Jarrott Cup Competition.
" 25-28—N.W. London M.C.C. and Herts. County A.C. Inter-club Trial to Harrogate and back.
28—Brooklands A.R.C. Easter Meeting (two events for motor cycles.)
30 to April 2—Exhibition of Motor Cycles. at Leicester Association Hall
April 13—(Wed.) B.M.C.R.C. Meeting.
" 20—A.C.U. Second Quarterly Trial
" 27-28—Brooklands A.R.C. Meeting
" 30—M.C.C. Members' Hill-climb.
May 4—B.M.C.R.C. Meeting at Brooklands.
" 4—Herts. County A.C. (motor cycle section) Open Hill-climb.
13, 14, and 16 (Whitsun)—M.C.C. London-Edinburgh and London-Edinburgh and Back Runs.
25 (Thursday)—International Motor Cycle T.T. Race in the Isle of Man.
" 27—Open Hill-climb in the Isle of Man.

Streatham and District M.C.C.

There will be a "breakdown" competition at the Crown and Sceptre Hotel, Streatham Hill, on Wednesday, March 9th, at 8 p.m. Small entrance fee. Local motor cyclists are invited to attend.

Newcastle and District M.C.

The annual meeting was held on February 26th, when Mr. Robson Crosier presided, and there was an excellent attendance. The first annual report showed a balance of £18. The report was adopted unanimously, and the following officers were elected: R. Crosier (chairman), E. Hawkins (secretary), W. H. Outwin, L. Austin, S. W. Carty, L. Rosevinge, H. Bradford, H. M. C. Bell, E. L. Bates, R. Ellis, J. F. Mallett, W. B. Kirsopp, R. Wilson, R. B. Smith, and A. D. Nicholson.

The Secretary announced that the club had become affiliated with the North-eastern Automobile Association. Prizes were then presented to the successful members in last year's competitions.

It was intimated that Col. Yorke (chief of the N.E. District Cycling Battalion) had promised to present a trophy to the club for competition.

Glasgow University M.C.

Next Saturday, at 2 p.m., a hill-climbing contest is to be held on the Peesweep Hill, Gleniffer Braes, Paisley. There will be six classes, viz.: Class I., single-cylinders (unlimited); Class II., multi-cylinders (unlimited); Class III., scratch class (singles up to 500 c.c., twins up to 750 c.c.); Class IV., sidecars and tricars; Classes V. and VI., for cars.

Edinburgh M.C.C.

The annual meeting was held in the Carlton Hotel on the 28th ult. The president, Mr. Norman Macmillan, occupied the chair, and a satisfactory report and balance-sheet were submitted by the hon. secretary and adopted.

Birmingham M.C.C.

The seventh annual general meeting will be held at the Imperial Hotel on the 12th inst., to be followed by a smoking concert, to which all motor cyclists in the district are cordially invited. The meeting will begin at 6.30 p.m. The programme for 1910 will be discussed, and a very active year is projected.

Herts County A.C. (Motor Cycle Section)

Next Saturday, at 3 p.m., the opening run takes place from St. Albans to Baldock and return. Tea at headquarters, the Red Lion Hotel, St. Albans, at 6.30 p.m.; tickets 2s. each. At 8 p.m. there will be the opening of the new clubroom, a Bohemian concert, and presentation of prizes. Ladies are invited.

Members of the University of Birmingham M.C.C. at the foot of Sunrising Hill on the occasion of the opening run.

Simplicity.

NO one will gainsay the fact that simplicity is the keynote of reliability. When applied to motor cycles it is particularly true; therefore a motor cycle should be as far removed from complication as it is possible for it to be without sacrificing the essential details which go towards making a perfect machine. The moment multiplicity of parts is introduced, reliability and accessibility must suffer. In trials and other forms of competition where reliability counts, other things being equal, it is usually the simplest machine that scores the greatest number of marks. The average motor cycle is certainly the simplest form of mechanically-propelled vehicle on the road, and it will become simpler as time goes on. Whatever direction improvement takes in connection with our mounts, let us always impress on those responsible for their design and manufacture, simplicity and again simplicity.

Speed and Multiplicity of Explosions.

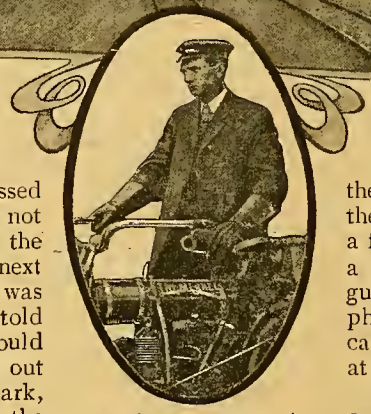
WITHIN a few weeks the riding season will again be in full swing, and this year more than ever motor cyclists will be seen in greater numbers on all the roads in the country. The increasing number of multi-cylinder machines in use and the introduction of two-stroke engines, either in twin or single-cylinder form, have made it necessary to point out that motor cyclists should endeavour to acquaint the police and others in authority that the sound caused by the exhaust of a high speed multi-cylinder motor cycle engine, possibly running on the low gear, does not mean that it is travelling at a speed in excess of the legal limit.

The foregoing has been inspired by an incident which recently came under our notice. A rider on a four-cylinder motor cycle, minus a silencer, passed the end of a street, close to where a policeman was standing, at quite a moderate speed. The officer, evidently judging the multiplicity of explosions as those emanating from a single-cylindered machine being ridden at an excessive speed, ran to the corner of the road and watched the motor cyclist gradually disappearing, and if we are not mistaken was just in time to secure his number. We then explained to him that the rider was not travelling at more than twelve or fifteen miles an hour, but, owing to the number of cylinders and the rapidity of the explosions, by which the officer told us he estimated the speed, he probably appeared to be travelling at about forty miles an hour.

Single-cylindered machines being in the majority, the public ear becomes more or less accustomed to the beat of single-cylinder engines, and both it and the police are likely to attribute reckless driving to the innocent owner of a multi-cylindered machine, which may appear to them to be greatly exceeding the legal limit of speed, when the rider is perhaps not travelling so fast in reality as others mounted on single-cylindered machines of whom no notice is taken. All motor cyclists will be doing each other considerable service if they will inform the police on all occasions that it is quite possible for the speed to be seriously overestimated solely by the fact that the number of explosions is four times greater at a given speed on one type of machine than it is on another. In the instance cited above the rider of course had no right to use his machine minus a silencer, and would have richly deserved a fine if he had been summoned, merely because he was making more noise than necessary.

ACROSS THE AMERICAN CONTINENT ON A MOTOR CYCLE

By Stanley Bowmar.



The first instalment appeared in our last issue.

Across the deserts and prairies, one's only guide for any sort of accommodation, water and supplies, is the railway line. Experience had not yet impressed this fact upon me, otherwise I would not have listened to the short-cut stories of the Laramie hotel folk. Fort Steele, the next town where petrol could be procured, was ninety-three miles away, and I was told that an excellent trail across country would lead me "right straight there." I set out gaily, confident of reaching, before dark, Elk Mountain Hotel, at the foot of the solitary mountain that gives the halfway house its name. A night in the sage brush was not the pleasantest of prospects. Luckily it was moonlight, and I plodded on, trundling over sandy hillocks and keeping my direction with a pocket compass. Between ten and eleven o'clock I came across a dilapidated ranch house. I was soon rummaging round, prospecting in the cupboard for something edible. Pots and pans and empty Milwaukee whiskey bottles were scattered round on the floor of what had evidently been the kitchen, but, other than an unopened packet of Quaker oats, the cupboard was innocent of even the proverbial bone. The hay loft over the barn was more tempting than the bedroom. Covering myself with hay, I made an effort to sleep. Inside, the rats, in battalions numerous enough to cheer the heart of a German Minister of War, romped and raced round about and over me; outside, the coyotes' dismal howls as they prowled around were just as insistent—and unwelcome.

The Cowardly Coyote.

The coyotes—the wild dogs of the American deserts—are the most despicable, miserable wretches in the whole animal tribe. They will not attack one; they are too big and cowardly for that. They delight to slink round, in a sneaking, cunning way, preying on weak sheep and lambs, sickly jack rabbits—on anything that cannot put up a fight, or even a decent struggle. At nights on the deserts their howls can always be heard, dismal in the extreme, like the wails of lost souls in the wilderness. Many a night when I have been trundling along, dead tired, wondering how far it was to the next section house or camp, their shrill howls have made the dead silence of the vast open spaces more intense and depressing.

I raided the packet of Quaker oats in the morning, then returned to the cheerless task of finding the trail. The summit of the only hill in the vicinity showed a dismal outlook. Undulating prairieland, broken here and there by clumps of stunted trees, as far as the eye could reach; the only sign of life a few scared cattle. Beyond these I noticed a smudge on the horizon—Elk Mountain, I guessed! So far away! In the clear atmosphere of the deserts of high altitude the eye carries far. I knew that the mountain was at least thirty miles distant.

It would be wearisome to detail the difficulties encountered during the day—at times trundling across country without the shadow of a track, riding where a heavy dray would scarcely have ventured; and in the evening, after I had intersected the trail, a river had to be forded.

Troubles and difficulties were never absent after I crossed the Rockies, but my experiences between Laramie and Fort Steele were probably the most disheartening. I reached the Elk Mountain Hotel an hour after dark, worn out. The landlady, a kind motherly person, brought me warm water to bathe my feet, and took charge of boots, stockings, and knickers, which had been soaked in the ford, and soon had ready a steaming hot supper.

Wretched Weather Delays Progress.

Lack of a decent trail had been my trouble the last two days; on the morrow it was wretched weather. The hotel folk predicted snow, and strongly advised a halt until the weather improved. The biting wind from the mountain was cold enough for anything; so cold, in fact, that the motor would not start on account of the piston sticking. So late in the season, however (it was then past the middle of October), every day lost lessened my chances of getting across Wyoming and Nevada before the winter snows and blizzards made the deserts uninhabitable.

Down a gorge with the rather suggestive name of Rattlesnake Canyon, I followed the trail, against a cutting gale. In spite of the down grade, the motor was twice blown to a standstill, and to walk against the wind was practically impossible. At the western foot of the mountain the track led into a vast plain of prairie; led, one could well imagine from the outlook, to some far away Nowhere, a Never Never Country, a billowy waste of stunted sage brush and sand. Heavy clouds in the south-west formed an inky background for the drifting sand in the valley.

An hour's riding, given a fair track, would have

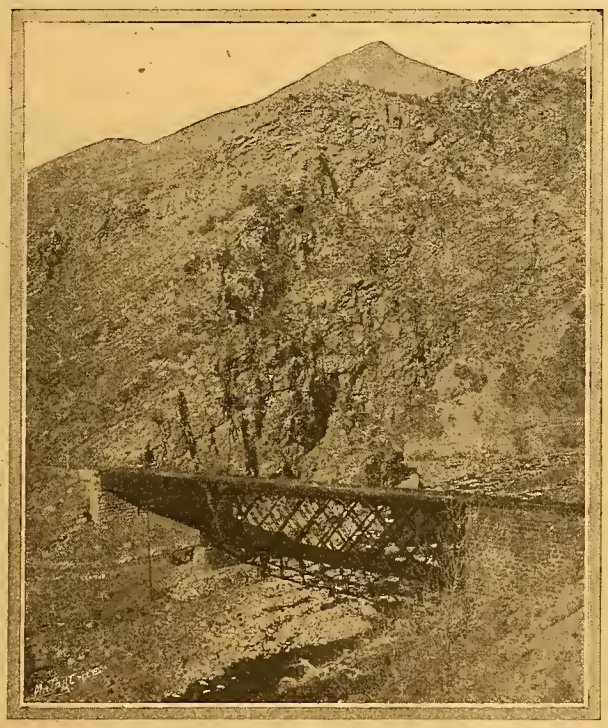
Across the American Continent on a Motor Cycle.—

seen me safely at Fort Steele. An hour's ride! Not one but five hours later I was still in the prairie, in a blinding snowstorm, soaked to the skin, half frozen, and no nearer to Fort Steele. It was impossible to follow the trail after the first snow had fallen.

Night found me, not at the town, but in a shepherds' camp, which I espied when the storm cleared away. Had it snowed until after darkness set in, I fear that it would have been necessary for those interested to advertise in some lost, stolen, or strayed column for one trans-Continental motor cyclist. Rigged out in dry clothes I thawed gradually by the shepherds' stove in their little house on wheels.

A Solitary Life.

In Nevada and Wyoming hundreds of shepherds spend all the year in their camp vans, always on the move, changing their districts according to the season. In summer they are to be found on the high grounds; in winter they shelter in the plains. There are vast areas in these states that have no marketable value; but where there is a little water, sheep and cattle will, if kept on the move, at least find sufficient "picking" to live. Many of the sheep and cattle men send out a man and a youth with a two-horse van, provisioned for three months, in charge of a flock of sheep or a herd of cattle to wander over these areas. At shearing time, or when prices rise in the Eastern markets, the sheep or cattle are driven back again to civilisation.



Over bridges like the one shown above, but on an infinitely larger scale, the trans-continental motor cyclist has to cross a number of rivers in the States of Wyoming and Nevada.

Not infrequently a state of war exists between the cattle and sheepmen. Sheep eat closer than cattle. If the sheepman encroaches on the cattleman's preserves, the cattle starve. These quarrels are sometimes serious. The roughest characters obtainable are engaged on both sides, and fatal combats are by no means uncommon.

The idea of motor cycling across the Continent paralysed my friends in the house-van. They could not have been more surprised had an aeroplane alighted in the neighbourhood, and I had to explain (as I had on many previous occasions) the mysteries of a motor.

"Well, I'll be durned," said one of the quaint old waybacks. "I guess it's as trickey as my old woman used to be."

So welcome did the shepherds make me that I was loth to leave. With not more than half a dozen favourite volumes, no worrying weeklies or newspapers, I can well imagine that a year of such aloofness and solitude as their life afforded would be a time of rich experience and splendid development, to a student.

The tanks recharged with petrol and oil at Fort Steele, I headed west, being careful to keep close to the railway lines. For the future short-cut suggestions simply did not interest me.

Miles and miles of the prairie land traversed has been arid enough. But my first real desert was ahead —the Red Desert, immediately west of Fort Steele. Instead of the sandy plain I expected, it was undulating—billowy, like the ocean when a big sea is running. The most impressive feature of the great deserts is the mighty silence and solitude that is so overwhelming. The wind, which in the daytime blows continually from the west, sings a mournful lonesome song in the telegraph wires, always sad and cheerless. There is no song bird—no living thing of any description, save a stray, sick-and-sorry looking coyote, which, with a furtive and evil glance at one, starts from his hiding place and quietly slinks away.

Often there was a thick coat of alkali over the sand, white as snow. The deep burning sand of the ordinary desert is bad enough, but the alkali flats are wholly accursed. The fine white dust penetrates one's clothes and plays havoc with the skin. My hands, hard as they were, soon cracked, and lips and ears and nostrils. The alkali flats, however, were firmer than the sand; it was possible to ride on them. Where the sand was soft, there was no alternative but to bump the ties between the rails—a proceeding calculated to wake up even the Solar Plexus.

The Great Divide.

A peculiar interest attaches to the Continental Divide, which I passed at noon next day, because if a spring should rise at this spot (which is not the least likely), it is said that its waters would divide, one half flowing to the Atlantic, the other to the Pacific Ocean. There is no Sweet Vale of Avoca, let me remind the reader, at the "Dividing of the Waters"—nothing but desolation and utter dreariness. A railway telegraph office and a section house have been erected there.

Every twenty miles or so along the Union Pacific Railway there is what is called in America a section house, where the repairmen camp—little outcast colonies of workmen, mostly Greeks, Italians, and Germans, with usually an Irish foreman, cut off from the world. The fast trains fly past, accentuating the sense of loneliness and isolation. In fact, the only tie with civilisation is the occasional call of a water train to fill the tanks and leave provisions. Their only visitors are tramps.

Motor troubles had caused a minimum amount of trouble west of Denver, but my good fortune in this respect forsook me farther west. A header on the

line broke a petrol pipe, and all the precious fluid wasted on the thirsty sand forty miles from Rock Springs, the nearest town. A forty mile walk! There was no alternative. An all-consuming thirst (I mean no irreverence) drove me almost mad as I trudged through the blistering sand. The sky was white with heat, and the sun's rays bounced back from the baked earth, and literally burned. Every gust of wind was like the breath from a liner's stoke-hole.

My petrol pipe soldered, another difficulty presented itself west of Rock Springs—the Green River was not bridged. They told me of this in the town, but said that the ford could be negotiated on foot, the river being unusually low. Why some people delight to give unreliable information in a positive, oracular manner that brooks no question, is a question that

A Californian orange ranch on the trans-Continental route.

comes up for solution with every stranger in a strange land, even in the Country of the Free. It troubled me in every State; the average American has a tendency to be so pugnaciously positive about everything.

The alternative of the ford was the railway bridge. Two fences had to be "got through" (I always carried a file), and the stars were out before I reached the bridge. Anyone who has seen an American railway bridge will know that invariably it has no side rails and that the planks do not protrude far at either side of the rails. I have seen it stated that if a train caught one on a bridge there was nothing for it but to do some practical trapeze work and hang from the ends of the planks. That possibly would be the safer way—for a man from a circus.

An Alarming Experience.

The Green River bridge is a long one. Before I started what was necessarily a slow, precarious walk, stepping from sleeper to sleeper and trundling the machine, I listened carefully. There was not a sound but the gurgle of the water against the piers; the night was as quiet as only a desert night can be. I would risk it. When a little more than half over, I noticed a tiny light in the distance, which quickly developed into the glare of an electric headlight of a fast train. Lifting the machine on to the outside of the rails, I laid it flat on the protruding end of the sleeper, the handle-bars and petrol tank well over the edge but balanced by the weight of the motor. Sitting on the edge of the sleeper, I shut my eyes and leaned over the water and hung on for grim death. With a rush, an alarming suction, and a shrill whistle, the train flew by. I have no doubt that for many a day the engine-driver will relate with gusto how he nearly scared the life out of a tramp one night on the Green River bridge. Subconsciously as I walked along gingerly, before I had an idea of the coming of the train, I had thought out what should be done in case I were caught. That possibly was my salvation.

More trouble was in store that night. Granger, the next town, was fifteen miles west, and the line was too badly ballasted for riding or for fast walking. In the small hours of the morning, after being turned away from one place as an undesirable tramp, I found a saloon keeper, who for payment in advance produced some bread and cold meat. He allotted me a bunk in a room with five others, one of whom expressed, in language more forcible than choice, his objection to my late intrusion on his drunken dreams.

The Fertile Utah Valley.

Utah. Would that I could adequately sing the praises of this State. What a relief to be where there were springs of cool, pure water; to see the autumn colours of the cotton woods, willows, and the evergreen pines, and the green hills and flower-strewn valleys! There was a welcome down grade from Evanston to Ogden, good roads, superb scenery down Echo Canyon. Instead of a monotonous waste, every nook and corner some industrous Mormon has converted into a prosperous farm. One hundred acres of Utah would be infinitely preferable to the whole state of Wyoming, all the towns thrown in as an extra Christmas inducement.

The Utah Valley is truly an oasis in a wilderness of desert. It is roughly situated right in the centre of the waste between the Rocky and the Sierra Nevada Mountains. Surrounded by the protecting Wasatch range, there are millions of acres of rich pasture, thousands of orchards, and areas, measured by the square mile, of towering corn. So far as my experience went, the hospitality of the people of Utah far exceeds that of any other State in the Union.

(To be concluded next week.)

In East Grinstead there is a baker who employs a boy to drive an old motor bicycle, apparently 5 or 6 years old, to which a carrier is attached, which serves to carry loads of bread he distributes during his daily rounds.

Talking of Tools

We would impress upon you that we have spent many years in a study of how best to carry them, and in the bags we have designed we claim to meet the Motor Cyclist's every need. Here are two—

B 9367.
The rearward extension takes its bearing against the Saddle springs, keeps the bag in an upright position, and utilizes an otherwise wasted space. This extension is formed into separate compartment with pockets for spares, and the bag is fitted with good pocket, loops for outfit, loose bag for sundries, and outside oiler pocket.

Its price is **12/-**; its size **8½ x 5½ x 4¾.**

B 5505. Strongly built for rear wear, fitted with roll-up (29 x 7½) with pocket at end, and supplied with two adjustable metal clips for attachment to carrier.

Price 14/-;
size 9½ x 5 x 3½.

There are many more in the BROOKS BOOK, of which we will send you copy on request.

The Choice of Accessories.

By B. H. DAVIES

THE Editor has asked me to write a short article dealing with the choice of accessories, and I can only emphasise facts which ought to be obvious, viz., that the accessories bought for use with any machine should be good in quality, and suited to the machine.

A machine is well equipped when it has a suitable selection of extra tools, lamp, and generator, hooter, spare tube in case, spare belt in case, luggage bag, and a speedometer. The tools in which most makers' kits are deficient are a good big spanner, a first grade screwdriver, and a valve spring remover.

Good.

It is a great mistake to save a few shillings by buying cheap accessories. There are lamps which fall to bits, generators which only burn an hour, hooters which bend or shiver their clips and cannot make a decent noise, leather bags and cases which melt when it rains, or have flimsy straps and rivets. Those riders who can make personal visits and select their accessories from the store of a large dealer should pay special attention to the nature of the fastenings, which can seldom be too strong and substantial. Country riders should get a selection sent down on approval. I always have quite a crateful of fittings and clothes down from town when I order a new mount. More than once I have returned its entire contents, and demanded goods of better quality. In time one comes to know whose waterproofs, whose lamps, whose horns, whose tools, etc., can be relied on.

Suitable to the Machine.

I shed the silent unostentatious tear when I see a Motosacoche carrying a 5in. Mangin mirror head lamp, or a £55 twin equipped with a cheap lamp that would hardly be fit for a £5 pedal bicycle, or a machine finished in nickel adorned with a brass hooter and head lamp, or a carrier full of paper parcels and small Gladstone bags, or a leather belt strapped on naked, smeared with mud, or a spare tube looped round the handle-bar. Such sights are not uncommon, and offend the eye.

Tyres.

The average rider will find that a rubber-treaded cover with pronounced studs or bars, or other anti-skid, is the most satisfactory for regular use all the year round; that jointed and butt-ended tubes are now perfectly reliable, and a great convenience in bad weather or when time is short; that such tubes ought to be stored in a specially designed case; and that the case needs broad and well riveted straps.

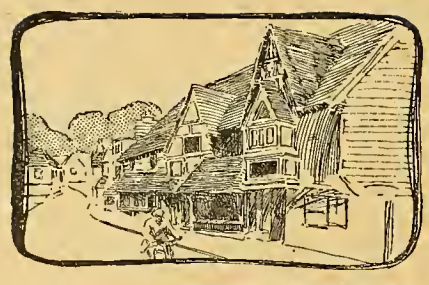
Clothing.

No colour is so well suited to all weathers as fawn. Many single texture garments are not drencher proof. A good price should be paid for a good article. The coat must be capable of being put on without contortions My last is an excellent protection, but it gives me cramp to put it on, and when it is on, my watch, pipe, and matches are inaccessible till it is removed again, and its removal affords a most laughable and undignified spectacle. The coat should be covert length at least, and the neck proportion is seldom adequate. Leggings are a large item in the balance-sheet of most all-weather riders. The fit-tight types look very neat, but few of them are designed with an eye to any but ideal feet. They are too narrow in the bore, and when a nailed boot is thrust down them; it either rips them to ribbons or seizes half-way. I have descended to a **large** pair of macintosh trousers. They look unsightly, even with cycle clips round the ankles, but I have grown aweary of stumping up 15s. once a month to replace torn breeks, and my stove pipe pair have lasted three seasons, just because the bore is wide enough to accommodate a No. 10 boot during the process of insertion. Overalls should be provided with a waterproof case for storage, otherwise the first downpour often wets them inside.

Toolbags.

Eschew the Saratoga trunk variety. There is one in my attic now. Its floor is covered with a kind of cement composed of carbide and lubricating oil. Embedded in the cement are some spare plugs, a valve, cotters, terminals, springs, studs, a toothbrush, a collar, etc. Now my oilcans spring into their own private clips. The tools have a bag to themselves; ditto the spare parts; ditto the personal luggage. When a late return is possible, the carbide tin goes in a side pocket, a small wallet of light tools goes in the other side pocket, and so forth. The family Noah's ark type of bag is dead out of date, and its place has been taken by several small bags disposed about the handle-bar, the tank sides, and the side stays of the carrier, leaving the carrier top and saddle back clear for a special suitcase of suitable dimensions when the machine is out on tour.

The meeting of the B.M.C.R.C. at Brooklands on Wednesday promises to be a great success, and it is to be hoped that a large number of motor cyclists will visit the track. The admission fee is one shilling.



CLUB NEWS

The Hull (Kingston) M.C.

The opening run is to Richmond, North Yorkshire, on Good Friday, leaving the Hayworth Arms, Newland, at 7.30 a.m. prompt.

North West London M.C.C.

The opening run is on the 20th inst., from Dollis Hill Lane, at ten o'clock, to the Rose and Crown Hotel, Tring.

Members who are unable to start for Harrogate in the inter-club competition should communicate with the hon. secretary, Mr. C. A. Stern, 14, Grove Road, Cricklewood, who will make arrangements for a party to start later—probably on Saturday afternoon.

WESTERN DISTRICT M.C. PAPERCHASE.

The "hounds" waiting for the eight minutes to elapse to take up the hunt.

The "hares" rode a Red Indian and a Triumph.

Newport (Mon.) and District M.C.C.

A general meeting was held at the Central Chambers, when there was a good attendance, and new members enrolled. The officers are: Captain, G. Scott; vice-captain, J. H. Foreman; treasurer, F. Purnell; hon. secretary, J. Pritchard.

The first run will be on Good Friday, to Hereford, leaving headquarters, Queen's Hotel, at 10 a.m.

The Newcastle and District M.C.C.

The club suggests holding team trials in conjunction with the opening run to Richmond on Good Friday. It is expected that this will bring out a few more riders than usual, and other clubs attending this and other meets might well follow this example. The Newcastle and District M.C.C. has found in the past that team trials are interesting, and very beneficial to the novice, as it very often happens that an expert and a novice are drawn together in a team, and the expert must get his novice home; consequently such trials can be looked to as a form of motoring education.

Manchester M.C.

Next Saturday the opening run takes place to Sandbach. The Easter tour commences on the 25th inst., to Beddgelert and Snowdonia. On Thursday next the return billiard match with the Liverpool M.C. will take place at Liverpool.

Cambridgeshire M.C.C.

The social evening arranged for to-morrow (Tuesday) will take the form of a whist drive. It is hoped that all members who possibly can will attend and take friends.

Shropshire M.C.C.

The second annual general meeting will be held on Thursday next, at the Unicorn Hotel, Shrewsbury. Any motor cyclist in the district desirous of becoming a member should send his name and address to the hon. secretary, Cecil Rice Oxley, Wheatlea House, Meole Brace, Shrewsbury.

Leicester and District M.C.C.

There was a splendid turn-out for the opening run of this newly formed club, and the run itself was a huge success. Thirty-six motor bicyclists, two sidecarists, and one tricarist started for Market Harborough, where tea was partaken of. (See photograph, page 231.)

On Sunday, the 20th inst., it is proposed that the members meet the Nottingham M.C.C. at Belvoir Castle. A hill-climb will probably take place in May, and there will also be runs to London and back and Skegness.

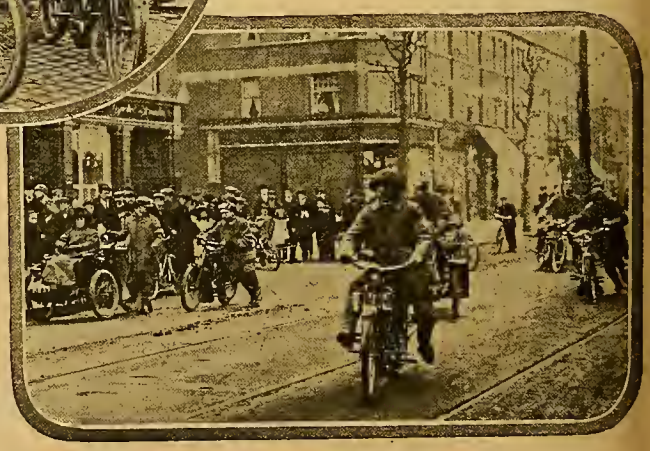
Middlesbrough and District M.C.C.

"Humorous Experiences with a Tricar" was the title of a paper read by Mr. J. R. Sorrell, jun., to nearly thirty members of the above club, at the headquarters, Corporation Hotel, Middlesbrough. The paper was written after a journey on the railroad to London and on the highway from London to Middlesbrough, and was a great success, the lecturer provoking much mirth by his witticisms.

Bishop Auckland, Darlington, and District M.C.

There was a good attendance of members at the club's headquarters, Wear Valley Hotel, Bishop Auckland, to hear Mr. N. Dewhurst's paper on "The Law and its Relation to Motorists." Mr. Dewhurst very clearly explained the numerous sections of the Motor Car Act, and drew attention to several very important points.

A hot-pot supper and smoking concert was held on Friday last.



The "hounds" starting off hot on the scent.

If you want the handiest, strongest, lightest, and most efficient lightweight motor cycle there is, order a

RELIABLE ACCESSORIES AT
London's Lowest Prices

THE NORTH ROAD DUST AND RAINPROOF OVERALLS.

These meet a long-felt want; they can be instantly slipped on over the ordinary trousers, they fasten round waist with a leather strap and buckle. Being made in one piece they are a great protection to the stomach, also it is impossible for the rain to drive in as with the ordinary overalls. Made in three lengths—short, medium, and long. Shaped to go over boot. Patent Side fasteners. Price, in fawn waterproof material, **16s. 6d.** Postage 6d.

Double texture waterproof coat with collar and rain and windproof sleeves to match above, **21/-.**

THE "ACME" WATCH HOLDER.

Will not rust. Made in aluminium. Will fit all handlebars. Complete with **Ingersoll** watch that is specially constructed to stand vibration. Watch can be set and wound without removing same from case. Each watch has a written guarantee given with it for 12 months. Price, complete, **8/6.** Case only, **3/6.** Post free.

THE LODGE PLUG.

Suitable for magneto or accumulator ignition. Spark brought well away from all cold metal surfaces, enabling **maximum power** to be obtained from spark and extremely weak mixtures to be fired. Three spark points and centre rod all of **absolutely pure nickel** and substantial in size. The spark will not burn them away. Porcelain sleeve round central electrode, which keeps hot enough to prevent the deposit of soot or any condensation, and this without the possibility of preignition common to plugs with projecting porcelains. Each plug guaranteed. Price **4/-.** Post free.

THE HUNT HELLESEN DRY CELL.

No corroding terminals. No acid. No charging. Always ready, clean, and dry. The **"Flash."** Height 6½ × 4 × 2½in. Approx. mileage, with siogle-cylinder engine, 1500. Price **6/6.** The **"Flight"** ditto. Height 5½ × 5½ × 2½in. Price **6/6.** The **"Midget"** emergency ditto. Height 5¾ × 4⅜ × 1⅜in. Will run approx. 300 miles. Price **4/4.** Postage 6d. extra.

BOWDEN HANDLE-BAR CONTROL LEVERS.

Single lever only, **4/6**; ditto, with 4ft. of combined cable and stop, **6/4.** Double lever, **6/-**; ditto, with two lengths each 4ft. of combined cable and two stops, **9/8.** Post free.

THE HUNT MAGNETO COVER.

Manufactured of best patent leather, far superior to rubber as it does not crack or perish. Will fit all types of magnetos.

Price **2/3.** Postage 2d. extra.

Protects the magneto from dust, dirt, rain, etc.

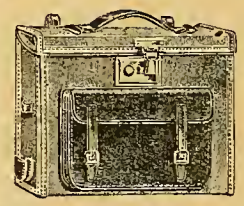
The **H.S. All-rubber Goggles,** including one set each of smoked and plain glasses. Price **1/11.** Postage 2d.

THE HUNT EXHAUST WHISTLE.

A splendid road clearer. Easily fitted. Operated by foot. Effective on one or two cylinders.

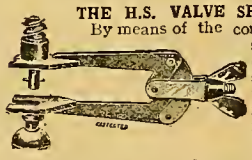
Price complete, in brass, with foot pedal, **10/6.** Post free.

THE "COMPACT" PANNIER BAG.



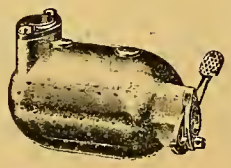
Manufactured of strong waterproof brown canvas, fitted with two small outside pockets to take oil can and petrol squirt, and large leather pocket for spares. It is adapted for strapping on the side of a Lycett tubular carrier. This bag will carry all tools, oilers, etc., also a spare tube and belt. Size 12 × 9 × 3in. Price **12s. 6d.** Carriage paid.

THE H.S. VALVE SPRING LIFTER.



By means of the compound action the stoutest spring is easily raised by a slight turn of the winged nut, leaving both hands free. Price **2/6.** Post free.

THE HUNT SILENCER.



Manufactured of aluminium. No back pressure. Very light. Guaranteed silent. Price **14/6,** with cut out **18/6.** Ditto, with whistle, **24/-.** Post free.

THE HUNT EXHAUST CUT-OUT.

Increases the power on hills. Easily fitted. Worked by the foot.

Price in brass with foot pedal, **4/6.** Post free.

HANDLE-BARS.

Best quality only. Length, 23ins. Price **6/9.** The **P.M.** pattern, as illustrated; length 18in., stem ⅞in. or 1in. Price **7/6.**

Postage on handle-bars **6d.** extra.

THE "COMPACT" TOOL ROLL.

Size 15 × 7½in.

A useful little accessory, keeps all the tools clean and separate. Can be carried in the ordinary toolbag, is fitted with pocket for spares, manufactured of soft pliable leather and has a strong leather binding strap.

Price **3/-.** Postage 2d.

THE R.O.M. PUNCTURE PROOF COMBINATION RUBBER AND STEEL NON-SKID COVER.

Give absolute immunity from skidding under any road conditions.

Are long of life, and yet resilient.

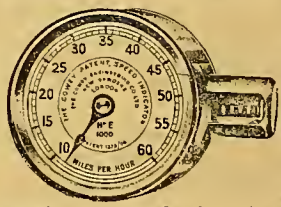
Are capable of being ridden equally well in summer or winter.

Present the greatest possible resistance to puncturing materials, and yet have no leather in its composition (leather making the tyre "dead").

Price, 26 × 2, **52/-**; 26 × 2¼, **55/-**; 26 × 2½, **57/6**; 24 × 2¼, **53/-**; 24 × 2½, **54/6-**; 28 × 2, **54/-**; 28 × 2½in., **60/.** Carriage paid.

THE COWEY SPEED INDICATOR AND MILEAGE RECORDER (Guaranteed).

Protection from Prosecution.—To the careful rider the Cowey is invaluable, for the exact rate at which the cycle is travelling can be seen at a glance, and it is impossible to unknowingly exceed the maximum legal speed. Motorists generally know the difficulty of correctly estimating the speed at which they are riding, and have been "trapped" when travelling—as they imagined—well within the limit.



Registers a speed up to 60 miles per hour. Mileage recorder registers up to 10,000 miles, then automatically starts again.

The indicator can be easily attached by any motorist, and once fitted requires no attention or adjustment whatever. It will continue to render good service as long as it is attached to the cycle, for it is constructed throughout of the best and most suitable materials by expert British mechanics at Kew Gardens.

Price, in Nickel, **84/-**, carriage paid.

THE NEW MODEL MUD PROTECTOR.

With Side Wings.

Manufactured of best patent leather, strengthened with iron supports. It is attached by means of thumb screws to front mudguard, and can be fitted to any make of machine in one minute; protects both rider and motor from all dust and mud thrown up by the front wheel.

Price **5/-.**

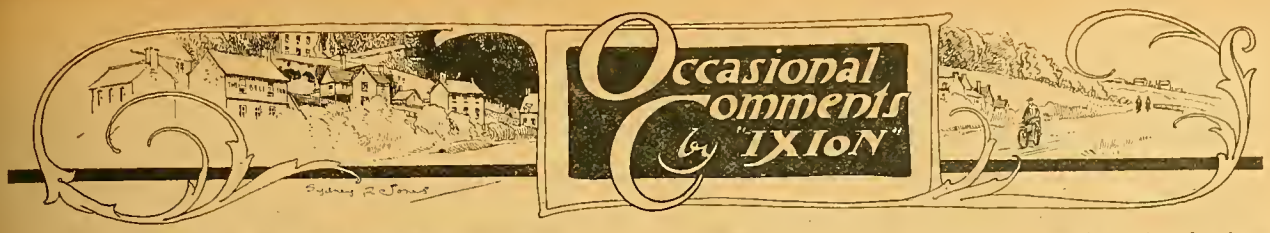
Postage 4d. extra.

THE "PATCHQUICK" REPAIR OUTFIT.

Containing "Patchquick" patches, which amalgamate with the tyre, and are not affected by heat

or friction. Used in conjunction with the "Patchquick fix," a repair can be executed that is equal to any vulcanising process. Price **3/-.** Post free.

A24 **Catalogue now in course of preparation.—Register your name and address for a copy, gratis and post free.**



Two Types of Machine in the Colonies.

The trade have yet to realise that two types of machine will sell in the colonies, and that of these one alone can expect a really large sale in the near future. Many of the machines such as we use on the old roads at home are mostly useless for business and touring purposes in the colonies. A genuine colonial roadster *must* have a variable gear, high power, great strength, large petrol capacity, and magnificent springing fore and aft. A big colonial market is impossible for any other type of machine at present. In the meantime a much more restricted market is open to machines which are practically *fac similes* of standard English types; it is this market which is being gently tapped by a few firms already, but these machines are seldom used for anything but short potterings in the neighbourhood of the more developed settlements. Their owners resemble the majority of American riders, in that regular cross-country work never figures in their experience. This market is certainly worth having, worth fighting for. But it does not compare in scope with the other market. Only a few comparatively well-to-do settlers will buy a machine for pottering within a twenty-five mile radius. Thousands of hard-working business men in the colonies will buy an efficient cross-country machine, such as will climb Amulree in any weather with certainty.

A Mission of Help.

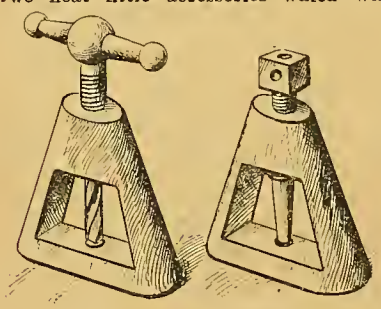
Several colonial riders have written to me during the last few months in very similar strain. They agree in asserting that very few colonial riders understand how good the modern motor bicycle is. The writers have been home quite recently, have sampled the opinion of English riders, and have tested first rate machines under home conditions, with the result that they have each taken back to the wild fastnesses of their respective homes in bush or on veldt an up-to-date machine. They assert that if colonists knew the capacity of the modern machine, the number of riders in South Africa, Australia, India, etc., would increase by thousands within a year or two. One enthusiast kindly invites me to purchase the mount I think most suited to the conditions he describes, and make a princely progress on it through the colony in which he resides—an area about double the size of Europe. He promises me a long round of lavish hospitality at the houses of keen riders, and suggests I shall lecture at various centres, and attend petrolic smokers at others. Nothing would charm me more, but neither my purse nor my engagements will allow of such a fascinating holiday. Nevertheless, I believe two or three of the big colonies are ripe for a visit from an expert rider, who, mounted on the best colonial mount that can be produced, should make a missionary progress throughout its length and breadth. I remember a Midland firm once sent out their crack rider on a mission of this sort, but the enterprise was premature. Nowadays we can make machines which could be of real use to the squatter, the Government official, the business traveller, and the colonial evangelist. I believe such an enterprise would repay a big firm already engaged in the trade. Failing such a firm, the tour would make a very pleasant outlet for the exuberance of sundry wealthy enthusiasts in our ranks who now spend their time in competitions at Brooklands and elsewhere. Will any enthusiast make up a party of keen and practised riders for a colonial tour in one of those big dependencies of the empire?

New Rules in the Six Days' Trial.

The only changes of any importance in the regulations for the Six Days' Trial are the raising of the minimum speed from 15 to 18 m.p.h., and the addition of a distinct penalty for loitering within a mile of controls. The first reform will penalise minor stops, and is therefore a sound innovation. It is a plagiarism from the Scottish Trials rules of 1909, when it worked very well; but it will press rather heavily on the riders unless the checkers get through their work more expeditiously than is their habit, and unless the petrol supplies are better engineered. Now that the riding time has been pared down a little, the men must not be delayed ten minutes at checking stations, nor must there be long delays in getting petrol; there may be considerable friction unless these points are well looked after. If the entry is large, there should be three checkers and three time sheets at every station, and the A.C.U. should invest in two or three dozen funnels, and loan them to the garages the men will resort to, each garage forwarding the funnels on to a garage along the next day's route as soon as the men have passed through. I do not say that riders are compelled to lose marks by such delays as I describe, but I do assert that the want of proper organisation in these respects compels the men to ride hard, and robs the trial of much potential pleasure. The second alteration is an advance, but scarcely goes far enough. It imposes a penalty of ten marks on any rider found within a mile of a checking station when ten minutes ahead of his schedule time. It imposes no penalty on riders loitering two miles outside a checking station. It will therefore be a dead letter unless the exact locality of the checking stations is kept a secret. If the checkers are posted at the familiar spots known to the older hands, the men will wait about three miles out of control instead of close at hand. If riders are warned that a check may be expected anywhere along a five or ten mile stretch, we shall see the machines keeping close to schedule all along the route, and we shall get a much more searching test of reliability. We do not want the ride spoilt, from a pleasure point of view, by entire secrecy as to checks, so that a rider never rounds a corner without fearing a check, at which he may lose a dozen marks or more; but we do not want continual scrapping, and we do not want men to have a loophole for unpenalised repair stops of varying duration in each day's run.

At this time of the year, when the whole of nature is about to burst into life, according to the calendar at any rate, great activity will be displayed in the ranks of motor cyclists. The machine ordered at the show has emerged from its chrysalis, and there it stands waiting for the first long ride for which dry roads will lend enjoyment. The first few preliminary spins give the rider the idea that several things are missing. His hands are cold, he needs to protect them; that old suit of overalls, torn perhaps and travel stained, does not go well with the bright plate and enamel of the new mount; a new lamp must be purchased, and a hundred and one odds and ends to add to the pleasures of motor cycling. We well know that most motor cyclists would like to visit each accessory maker in turn and select his own wares, but to very many this pleasure is denied. Consequently we need offer no apology in bringing this accessory and equipment issue before our readers. No expense or trouble has been spared to make both drawings and descriptions as clear as possible, and no stone has been left unturned to unearth novelties which are always cropping up from time to time. The study of accessories is also an interesting one, as the numerous items designed to add to the convenience of the rider display much ingenuity, cost comparatively little, and often as not their fitting on the machine gives as much pleasure as the use of them when ultimately *in situ*. To prevent confusion and enable readers more readily to find what they want we have classified the various articles under the following heads: Accessories, Equipment, Tyres, Electrical Appliances, Lamps, and Riding Apparel.

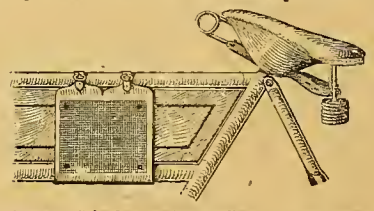
Mr. Anderson holds an advantage over many of his rivals in that he has been in the motor cycle trade for over ten years. In fact, he first showed his belts at the Crystal Palace show in 1899, so he may justly be considered a pioneer. At present he makes a speciality of the Elswick belt (a sturdy leather accessory) and the Gnaviter rubber belt (an equally serviceable contributory to the motor cyclist's welfare). A mere glance at these two belts shows their utility and strength, and Mr. Anderson's long experience in the trade is sufficient to guarantee their worth. He also specialises in two neat little accessories which will



Anderson's Belt Punches.

be useful to every motor cyclist, *e.g.*, a belt drill and belt punch. These are compact devices which take up but little room in the toolbag, and weigh practically nothing, while they may easily repay the small initial outlay in purchasing them, in one short run. Many kinds of wires, including electrical cables, control wires, etc.—in fact, there are 125 different kinds for all purposes—and cleaning materials, including Gnaviter wiper, conclude the special lines marketed by one of the first firms to cater for the motor cyclist. (F. L. Anderson, 1, Furnival Street, E.C.)

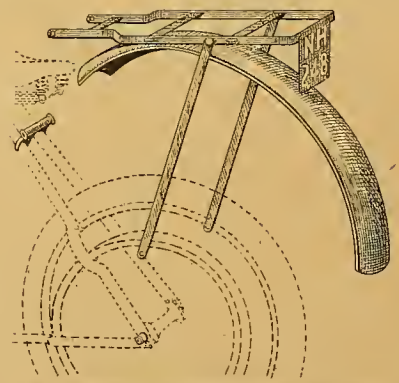
Most riders will discover, if they examine their tanks, that their knees unconsciously grip the tank sides when travelling fast, or in emergencies, and that, in course of time, a patch of the tank gets worn bare of enamel. The latest accessory is a rubber pad, strapped over the top tube, intended to protect the tank at these points. It



A Knee Grip for motor cyclists. It prevents the enamel being rubbed off the tank.

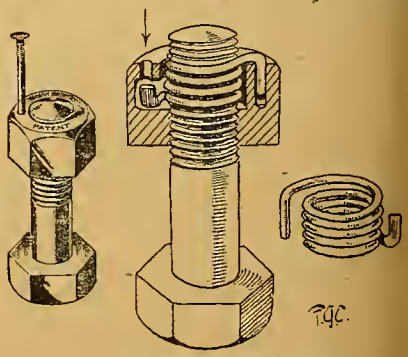
will doubtless find favour among riders who are particular about the appearance of their mounts. (A. K. Mfg. Co., 35, Swain Street, Bradford.)

In addition to the Advance adjustable pulley and belt fastener, the firm make a detachable luggage carrier and mudguard. This enables the luggage carrier and mudguard to be taken clear away from the back wheel when it becomes necessary to repair a puncture. With these obstructions out of the way it is, of course, much easier to remove the cover and patch the air tube—an operation which often necessitates taking out the back wheel in the case of machines with carriers. It is also an advantage when cleaning the machine. It can be fitted to any make of motor cycle, provided the distance between the back stays and mudguard bridge and diameter of wheel are given when ordering. The makers also supply a number plate with the carrier, on which the registered number of the machine will be painted if the necessary instructions are given. (Advance Motor Mfg. Co., Ltd., Louise Road, Northampton.)



The "Advance" Detachable Carrier and Rear Mudguard.

The Automatic lock nut is clearly illustrated by the accompanying line drawings. The nut is locked by means of the coiled spring which encircles the thread on the bolt. This spring exercises a constant grip on the thread



The "Automatic" Lock Nut.

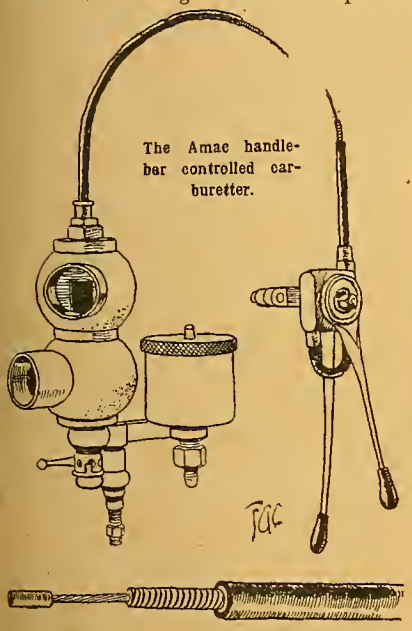
and prevents the nut turning back. If it be necessary to remove the nut the pin shown is inserted in the hole on the top of the nut, and pressure exerted on the spring which partly uncoils it, and allows the nut to be turned backward. (The Automatic Lock Nut Co., High Street, Birmingham.)

The Ideal ball bearing spring handlebar for motor cycles is an excellent device, with which we have had some experience, and therefore are in a position to recommend it with confidence to our readers. A lug on the bar enables it to be connected to the

Accessories and Equipment.

stem by means of an adjustable ball bearing, thus allowing a radial movement controlled by a coiled spring carried in a pocket formed on the lug on the stem. Any lateral loss of rigidity is taken up by the adjustable ball bearing, and in practice the steering of the machine is not affected in the least degree. Shocks which are often apparent even with the best spring forks are practically absorbed by this spring handle-bar, and do not reach the rider's arms. Of late these handlebars have been considerably improved, and also reduced in price. (S. Allen and Co., 8, Elswick Court, Northumberland Street, Newcastle-on-Tyne.)

The Amac carburetter is a device which is now so well known to our readers that a lengthy explanation is unnecessary. The most novel feature about the 1910 pattern carburetter is the method of carrying one of the control cables through the other, so that only one cable is visible on the machine. Among the other special

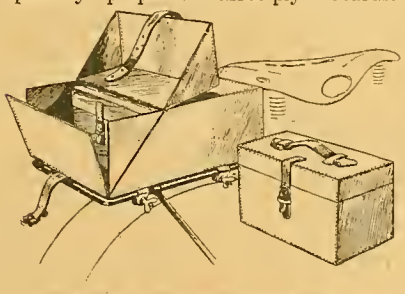


The Amac handle-bar controlled carburetter.

Showing the arrangement of control wire and cables

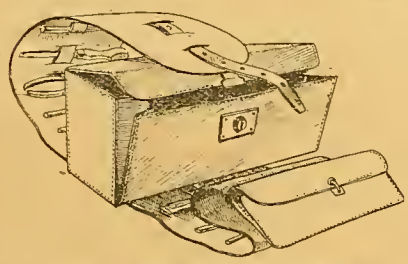
features of the Amac are a variable jet, by means of which it is possible to vary the amount of petrol passing through the jet orifice without dismounting, an improved system of air inlet by means of which a solid column of air is drawn up the centre of a tube which is fixed in the centre of the jet tube. The result of this ingenious arrangement is that the solid column of air and the hollow column of petrol meet together as they issue from the tubes, and are further mixed by colliding against an inverted cone at the top of the mixing chamber. Of course, air is drawn in *viâ* the usual choke tube in addition, but all the air enters the mixing chamber by one inlet. The ordinary jet and choke tube are supplied in place of the special one if desired. The Amac carburetter is beautifully made, and is an accessory which is fitted to a large number of up-to-date models. (Aston Motor Accessories Co., Ltd., Aston, Birmingham.)

One of the latest introductions is the Brooks motor cycle carrier bag, B9682. This bag is made with removable inside cases, and both these and the bag itself are manufactured throughout of best quality waterproof canvas on specially prepared three-ply boards.



The Brooks Motor Cycle Carrier Bag, with removable inside cases. The smaller of the two is for spares, the larger for clothing.

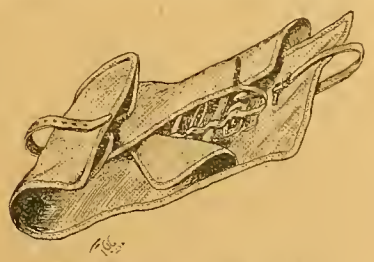
The two cases are of different sizes; the smaller of the two can be used for spares, tools, etc., the larger for clothing, and both, at the end of the journey, can be taken from the outside bag in a perfectly clean condition and ready for immediate transmission to the rider's room. That is an advan-



A combined Tool Roll and Case made by J. B. Brooks and Co., Ltd. The tools shown are not supplied with the roll-up.

tage best appreciated at the end of a long day's run, and we have no hesitation in saying that the adoption of this bag will add materially to the rider's comfort and convenience. (J. B. Brooks and Co., Ltd., Great Charles Street, Birmingham.)

Two items particularly appealing to motor cyclists are the Broadhurst tool rolls. These are strongly made of brown waterproof material with the edges bound to prevent wear. We

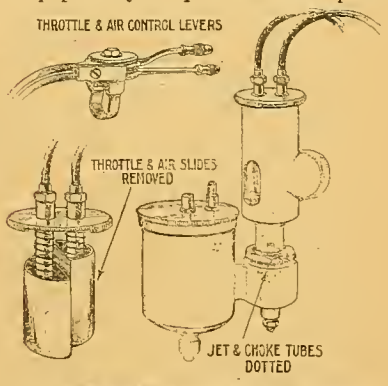


Broadhurst's Motor Cycle Tool Kit.

illustrate the larger of the two rolls, which contains twelve different tools of excellent quality and workmanship. The smaller roll has half a dozen less tools, but is otherwise of equal quality. The articles comprised in the larger roll are adjustable spanner, pliers, magneto knife, two box spanners, screwdriver, belt drill with clamping screw to hold belt in position, punch, oiltin, and right angle screwdriver for two positions. (R. Broadhurst, 25, Smithford Street, Coventry.)

The number of uses for bifurcated rivets in the construction of a motor cycle are numerous. Belts can be repaired with them. They are useful for making joints on straps, tool-bags, and other leather articles. We have even seen them used for attaching splashguards. These rivets are self-piercing, and can be obtained in boxes with and without washers. They enter largely into the construction of non-skid tyres, and as a box containing a gross with a tool for inserting and clinching them can be obtained for a trifle, they are a useful addition to any motor cyclist's home tool-kit. (Bifurcated and Tubular Rivet Co., Ltd., Gripwell Works, Warrington.)

One of the best known and most accessible carburetters with handle-bar control is the Brown and Barlow. Its popularity is quite sufficient proof

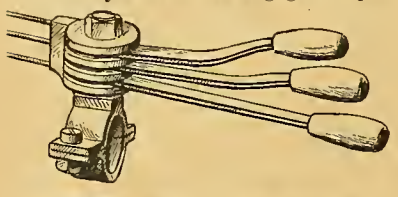


The 1910 Model Brown and Barlow Carburetter.

of its efficiency. Without lengthy description it will suffice to point out that the principal 1910 improvements are a bayonet-jointed top to the spraying chamber, which enables the throttle and air slides to be withdrawn for inspection by merely revolving the cover plate a quarter of a turn. The method of attaching the carburetting chamber to the float chamber is also made with a view to rapid dismantling. Half a turn of the hexagon nut shown surrounding the dotted lines of the jet and choke tubes is sufficient to release the spraying chamber, which is held in position when the nut is tightened by means of a conical contracting sleeve. The throttle and air control levers are extremely neat, and the jet can be removed in less than a minute by screwing it out from the underneath. If desired the makers of this excellent carburetting device supply a neat case containing four spraying jets of various sizes enabling the rider to tune his engine up for hill-climbs, consumption tests, or long-distance tours. (Brown and Barlow, Ltd., Holt Street, Birmingham.)

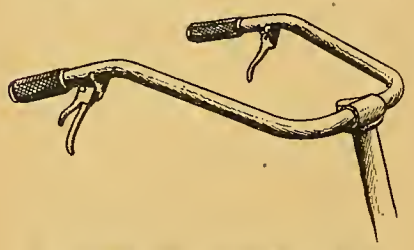
Accessories and Equipment.

It is largely owing to the enterprise of the Bowden Syndicate that handle-bar control has become so popular on motor bicycles. Towards the end of 1903 the syndicate was engaged in per-



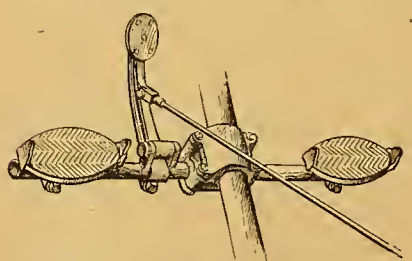
Triple Bowden Control Levers for throttle, air, and magneto advance.

fecting what has been one of the greatest boons with which motor cyclists have ever been favoured. In the last six years or so great improvements have been made, and it is interesting to note that nearly every machine at the Stanley Show was fitted with some form or other of the Bowden control, which has greatly simplified the handling of motor cycles, particularly on hills. The same company make a speciality of a triple set of levers with celluloid tips, conveniently placed so that any lever can be moved sepa-



The Bowden "clean" Handle-bar. The cables are threaded through the bars and issue at the lug in centre.

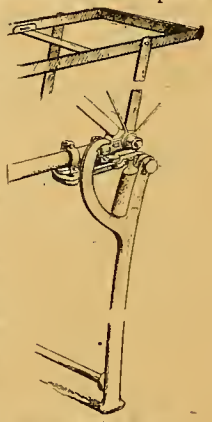
rately, which allows the spark, air, and throttle to be easily operated. The neat arrangement of the levers is clearly shown in the adjoining illustration. How neatly the Bowden control can be fitted to a modern motor bicycle may be seen by the above illustration of the "clean" handle-bar, in which the wires run through tubes and issue near the stem. The control of the magneto advance with the aid of a handle-bar lever is somewhat of a novelty which has lately been brought out by



Brake Pedal, Rod, and Foot-rests, one of the Bowden Syndicate's many accessories.

the company. Yet another novelty is the Bowden belt rim brake, which is operated by means of a rod. The accompanying illustration shows the control pedal attached to the footrests of the machine, the whole being a speciality of the Bowden Co. It will also be noticed that the pedal can be moved about and adjusted in almost any direction. (E. M. Bowden's Patent Syndicate, Ltd., 29, Baldwin's Gardens, Gray's Inn Road, W.C.)

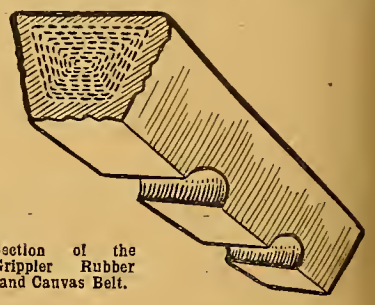
One of the most practical motor cycle stands on the market at the present time is the Bradbury, which possesses the advantage of being British made, of being rigid, safe, and very quickly put into action. It clips on to the chain stays, and thus enables the back wheel to be easily removed. The movable arm on each side has a slot cut into it, and attached to the fixed portion is a tube containing a spring plunger. To put the stand into action it is only necessary to kick it down with the foot, place the foot against the transverse bar and jerk the machine back, when the machine rests firmly on the stand. To place the stand out of action the machine is pushed forward, when, on the stand being put in its normal position, the spring bolt drops into the slot and it is impossible for the stand to fall down. The Bradbury stand can also be supplied with a luggage carrier, which does not in any way interfere with the latter. Now that the use of two-speed gears is on the increase there is a greater demand for footrests, and Joseph Bradbury has brought out an excellent pair of spring suspended footrests, which can be fixed to any machine, and, when fitted, can be adjusted to any angle to suit any height of rider. The rests themselves are covered with rubber matting, and are suspended on spiral springs. Another useful tool is the Bradbury valve spring lifter, which, by means of its compound action, enables the stoutest spring to be easily raised by a slight turn of the wing nut. Other specialities manufactured at the works at Braintree are excellent sets of tube spanners and other tools. (Joseph Bradbury, New Street Works, Braintree, Essex.)



The Bradbury combined Carrier and Stand.

The latest innovation on the part of the Chater-Lea Co. is a new plate clutch which supplants the old leather to metal clutch, and used on their three-speed motor bicycle. This new clutch contains thirty-eight spring steel plates, and like others of its kind possesses the advantage that it can if properly lubricated in the first place be slipped for some considerable time without damage. It possesses a groove which is cast on its outer shell to take a band brake, which allows the brake to be applied when the engine is in gear through the gearbox. The advantage of this is that when descending a long and steep hill the exhaust valve may be lifted, and in addition to the retarding effect set up by the internal friction of the engine and geare, a further gentle yet effective checking action may be applied. The footbrake rod connections on some of the machines have been very neatly arranged. We were also shown a very practical spring fork to which a front rim brake can be fitted; it was lately described in these pages. (The Chater Lea Mfg. Co., Golden Lane, E.C.)

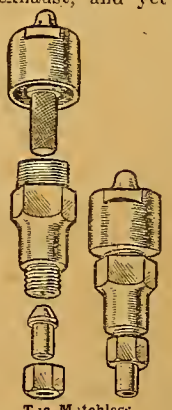
Grippler rubber belts are being marketed now by the Bancroftian Co.



Section of the Grippler Rubber and Canvas Belt.

These belts have a canvas core, and are exceptionally strong, though not expensive. Another accessory is a well-designed plug. The chief feature of the Bancroftian sparking plug is that the porcelain is hand-ground and not moulded, this process making it more immune from cracking. (The Bancroftian Co., 49, Bishopsgate Street Within, E.C.)

Two patterns of spring forks are sold by Collier and Sons. One is the Matchless girder spring fork—a scientifically designed contrivance which effectively absorbs the road vibration, allows a front brake to be fitted, and is totally devoid of side play. The Matchless spring fork attachments, which have been some years on the market, are chiefly suitable for bringing an old pattern machine up to date. The Matchless silencer is another excellent invention: it is most effective in deadening the noise of the exhaust, and yet it is devoid of back pressure, since with it fitted Matchless motor bicycles have scored heavily in hill-climbs, and have made remarkably good performances in speed events. The Matchless adjustable pulley when worked in conjunction with the firm's ingenious adjustable belt fastener are two further inventions of great interest. The pulley has slots of various sizes cut on the fixed portion, and in the movable flange there is a pin engaging in these. To alter the gear, it is only necessary to press in the outer flange and engage the pin in the slot giving the desired ratio. No tools are required. This firm has carefully

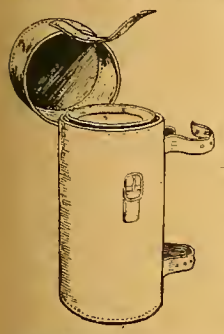


The Matchless Petrol Filter.

Accessories and Equipment.

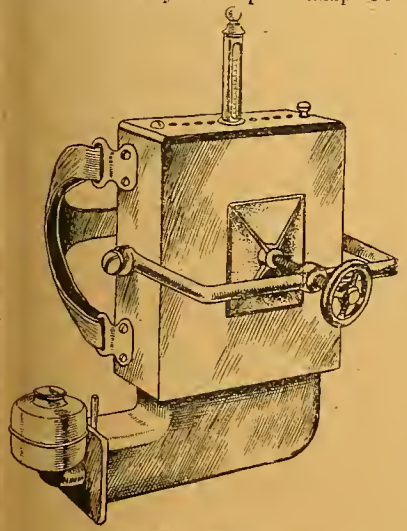
studied the question of brakes, and sells several excellent types which are applied to the belt rim. Two patterns of these are sold complete with footrests, on which the control pedal is fitted. In addition to many other useful accessories sold by this firm, there may be mentioned the Matchless petrol filter, which is neat, small, and light—an accessory which should be found on every up-to-date machine. Besides the above advantages, it is easily dismounted for cleaning. (Collier and Sons. Ltd., Herbert Road, Plumstead.)

It is often necessary to make a short *détour* from the route planned in search of fresh supplies of carbide, either because the lamp has not been replenished previous to starting, or the container will only hold sufficient for a few hours of night riding. To overcome this difficulty, the County Chemical Co., one of the best known firms in the trade, who supply excellent calcium carbide, have introduced a small leather case for carrying a ½ lb. tin of spare carbide. The tin fits the case exactly, and the latter is strapped to some convenient part of the frame, such as the seat tube below the tank. ½ lb. tins of carbide are not easily introduced into the dimensions of an ordinary toolbag; therefore this little case should appeal to those who have much night riding to do or who are apt to forget to replenish the generator.



The Conty Chemical Co.'s Case for carrying a ½ lb. tin of spare carbide.

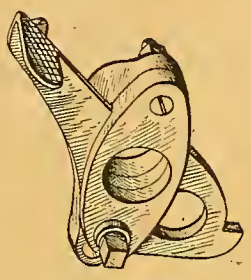
The G.B. vulcaniser consists of a cast aluminium generator heated by a small detachable methylated spirit lamp on the principle of the Bunsen burner. A thermometer is provided to register the temperature. This is fitted to a perforated plate, by means of which the heat can be regulated. It is suitable for all sizes of motor cycle covers and air tubes, and is beautifully made, although not expensive. The same firm are well known as makers of the G.B. motor cycle tyre repair outfits. (County Chemical Co., Bradford Street Works, Birmingham.)



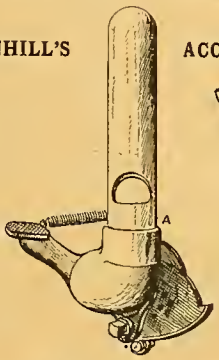
The G.B. Vulcanizer.

Dunhill's stock a large variety of motor cycle valises to be strapped to the rear carrier of the machine. The valise will carry sufficient clothing for one night, and the flaps are provided with pockets for maps, etc. The material consists of compressed fibre which is thoroughly waterproof.

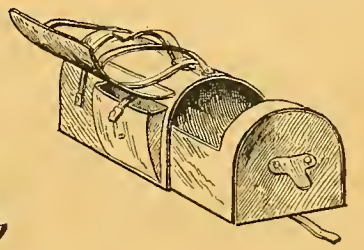
THREE OF DUNHILL'S ACCESSORIES.



A simple Exhaust Cut Out.



A Combined Cut Ont and Exhaust Whistle. The whistle unscrews at A to facilitate cleaning.



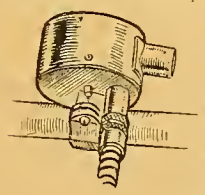
A neat Touring Valise.

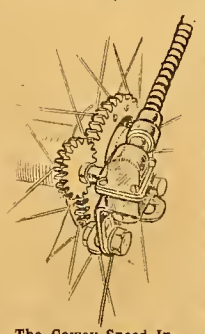
Several patterns, sold at different prices, are obtainable. In addition to the above, other interesting accessories are—a new cut-out, a motor cycle exhaust whistle, designed to be clipped on to the exhaust pipe and to be operated by the rider's foot, and a lens mirror lamp and generator. (Alfred Dunhill, Ltd., Euston Road, N.W.)

The Continental motor cycle belt of rubber and canvas carefully made to the correct angle of 28° is a remarkably reliable article, and is manufactured in sizes ranging from ⅝in. to 1in. The Continental belt punch is also an ingenious and useful accessory, as it is suitable for all sizes, and is fitted with an adjusting screw which presses the belt up to the top when the larger belts are used. Two other very useful accessories are the Continental rubber magneto cover, and a tyre puttee for the temporary repair of a badly gashed cover. (The Continental Tyre Co., Ltd., Clerkenwell Road, E.C.)

In the issue of November 3rd, 1909, reference was made to the practice of fitting a brake control pedal on the footrests, as in the event of the latter becoming damaged there was no means of operating the brake. Chase Bros., well-known as record breakers a few years ago, have in their latest brake brought out a dual control. The control pedal may be fitted either to the footrests or any convenient part of the machine, and at the same time a back-pedalling system is incorporated, so that in the event of the footrests becoming damaged, the rider has still means to apply his brake by back-pedalling. Also no matter whether the rider's foot is on the pedals or on the rests the brake is always ready at hand. In addition to the above, Chase Bros. make a back-pedalling brake only, and a compound brake, the control pedal of which is attached to one of the crank case bolts. (Chase Brothers, Station Road West Croydon.)

One of the most popular motor cycle speedometers is the Cowey. This instrument works on a different principle from most others. It is composed mainly of three fundamental parts—a heavy balance wheel, a spring, and a propelling device. The spring is connected up to the balance wheel by means of a small chain in such a manner that it tends continuously to draw the balance wheel in one direction (the direction of zero on the dial), while the propelling device gives a series of intermittent impulses to the wheel which tend to draw it in the opposite direction. The faster the machine travels, the more numerous will be the impulses given to the balance wheel by the propelling device, and the spring, having more work to do in overcoming the effect of these impulses, will be deflected and allow the balance wheel to be angularly displaced to a greater or less extent. The balance wheel, in its turn, operates the indicating pointer and moves it into a position which represents the speed at which the motor cycle is travelling. In actual practice the indicator is found to be equally steady on good and bad surfaces, and to be most reliable. The machine is of a handsome appearance, and easily read. An odometer is fitted to each model. The instrument is easily attached to any machine, whether fitted with spring forks or not. (The Cowey Engineering Co., Archer Works, Kew Gardens, S.W.)

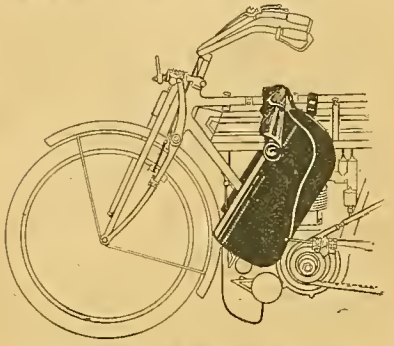




The Cowey Speed Indicator. The sketches show the gear driving mechanism attached to the front hub. The indicator is clipped to the handle-bar.

Accessories and Equipment.

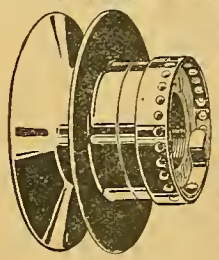
A type of weather guard which we have proved to be very efficient in keeping mud and wet from the rider's legs is the Cameron. One end of each guard is attached to the footrests and the other to suitable supports bolted



The Cameron leg shields. Note the waterproof apron, rolled up and strapped to the shield attachment on top tube.

to the top tube and hanging each side of the petrol tank. A weather-proof apron can be drawn over the knees and upper part of the body from a point near the top of the shields. When the apron is not in use it can be rolled up and fixed to the top of the shield by two straps as shown in the accompanying illustration. (Cameron's Weatherguards, 30, West High Street, Inverurie, N.B.)

The Clyno adjustable pulley is one of the easiest to manipulate and adjust, the movement being obtained by means of inclined planes on the faces of the sliding flange and collar. Holes are bored round the rim of the adjusting collar, in which engages a pin fixed to a circular spring, the spring being mounted on the main boss of the pulley. To adjust the pulley the long spring must be released with the finger and the collar turned either to the right or left, thus raising or lowering the belt in the pulley groove. The same firm also make an adjustable stand composed of one tube sliding in another, which can be locked at different heights, thus enabling the machine to be firmly supported on sloping or uneven ground. (The Clyno Eng. Co., Thrapston.)

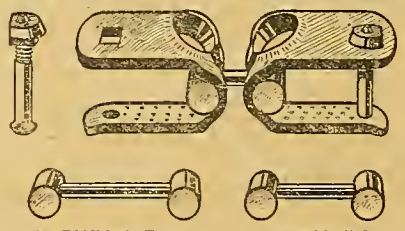


he Clyno Adjustable Pulley.

Hill's horn handle-bar grip is one of the refinements of motor cycling, as it is intended to prevent fatigue to the hands caused by gripping the handle too firmly. It is certainly a great boon to riders who wear woollen gloves, as it prevents the hands slipping off the ends of the bars. It has no square end to dig into the palms, which is always an annoyance to riders who indulge in long-distance riding. (Hill Bros., 32, Broom Close, Sheffield.)

Hill's Patent Handle Grip.

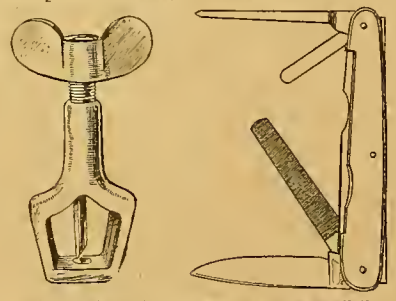
A belt fastener which is easy to connect and adjust is the D'All, which takes its name from the maker, Mr. J. B. Dall, of Ladybank, Fife. The outstanding features of this fastener are deep indentations on the inner faces of the jaws and curved ends to the bottom jaws. The former enable the belt to be gripped tightly, and remove some of the strain from the pin or bolt. The latter stop the cutting of the belt at the points where the jaws stop, the belt being very prone to cut when fastener is rounding the pulley. A special extension link is provided for use with adjustable pulleys. Electrical welding comes into the manufacture of this fastener, the connecting H links being made up of rollers electrically



The D'All Belt Fastener with adjustable links.

welded to short pieces of steel wire. Another device by the same maker is a combined gauge, injector, and tank syphon, which can be fitted to existing tanks by any amateur. No soldering is required, and it can be done without spoiling the enamel of the tank. It was recently illustrated and described in these pages. (J. B. Dall, Commercial Road, Ladybank, Fife.)

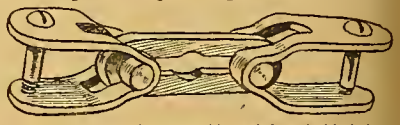
The firm of T. R. Ellin has been known for many years as makers of high-class tools. The two which appeal to motor cyclists are the small knife with file, etc., suitable for cleaning contact points, and a belt drill with the drill portion made like a carpenter's quill bit. The illustrations speak for themselves. (T. R. Ellin, Footprint Works, Sheffield.)



The "Footprint" belt drill and motor cyclist's handy pocket knife.

The Harrison back rest with automatic action was recently illustrated and described in these pages. It was exhibited at the Manchester Show and met with keen appreciation. Many tried the device, and we are informed by the makers that the universal opinion of riders was the necessity for a back rest on long journeys. (Harrison Automatic Back-rest Co., 205, Corporation Street, Preston.)

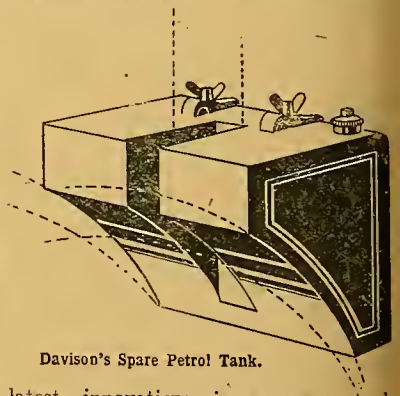
The Forward belt fastener is both detachable and adjustable, the adjusting links, three in number, fitting in slots in the clips. To insert a link it is placed vertically in the slot of the clip, the special grooved roller is



The "Forward" adjustable and detachable belt fastener.

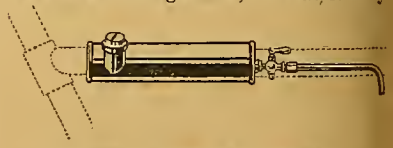
then inserted in the centre of the link, and the link pulled to the end of the slot, the remaining clip is inserted in the same way. Our illustration shows both clips in position on the longest link. (The Forward Cycle Co., 9, Edmund Street, Birmingham.)

From the very earliest days of motor cycling Mr. A. C. Davison has carefully studied the wants of motor cycle riders, and in consequence has succeeded in placing on the market numerous accessories of a thoroughly practical nature. One of the firm's



Davison's Spare Petrol Tank.

latest innovations is a spare tank holding a gallon of petrol, designed to be attached by clamps secured by winged nuts to between the end of the carrier and the mudguard. A black square is painted on the back, on which the number may be painted. The Davison paraffin tube is a handy way of carrying this useful medium for freeing the piston rings. It is attached by clips to a convenient frame tube, and has a small filling screw, so that it may



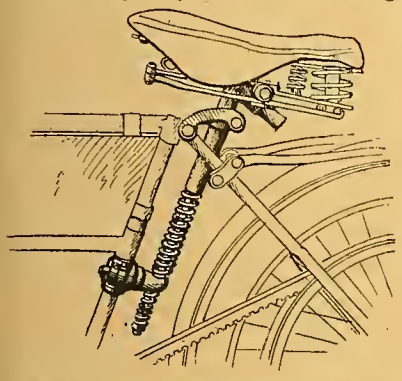
Davison's Paraffin Tube with tap.

be replenished without removal. At its further extremity it is provided with a tap and a conveniently curved tube. (A. C. Davison, 12a, Pleasant Row, Camden Town, N.W.)

The Perfecta spring seat-pillar, which is designed to fit all makes of motor bicycles is, in reality, a spring support designed to take the ordinary saddle-pillar. Mr. Cheswright, who with his brother manages the London business of the well-known firm of ignition specialists, Messrs. Lacoste and Co., is responsible for the produc-

Accessories and Equipment.

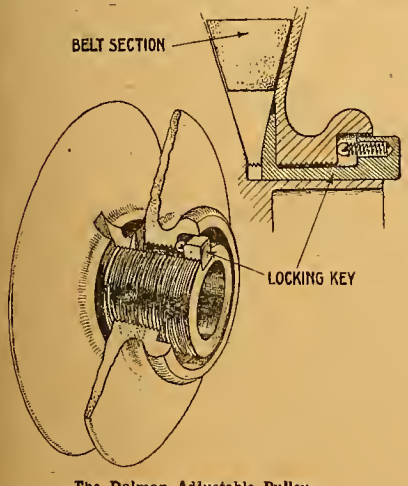
tion of this spring seat-pillar of excellent design. It consists of a tube to which a rod is attached, hung on two hangers secured by a bolt passing through the saddle lug of the frame; two small steel rollers act as bearings and allow the bolt to be tightened in the ordinary way without interfering



The Perfecta Spring Saddle Pillar, made to suit any pattern of motor cycle.

with the free movement of the hangers. The plunger rod referred to passes through a bearing clipped to the saddle tube of the frame, and has a spring above and below the latter, one acting under compression and the other acting as a check spring to counteract too sudden a rebound. Two models are manufactured, Model A for a machine having a clearance of 1¼in. or over between the back forks of the frame, and Model B where there is insufficient clearance. The support springs are also supplied in various tensions to suit the weight of the rider. With such a device as the Perfecta spring seat-pillar no motor cyclist need fear the effects of road vibration. (L. Cheswright, 184, Shaftesbury Avenue, W.C.)

The Dalman adjustable pulley is made on rather novel lines. Reference to the line drawing shows that the pulley consists of very few parts. There are the usual fixed and loose flanges, a spring controlled locking key, one spring, and one bolt, that is all. To adjust the loose flange the



The Dalman Adjustable Pulley

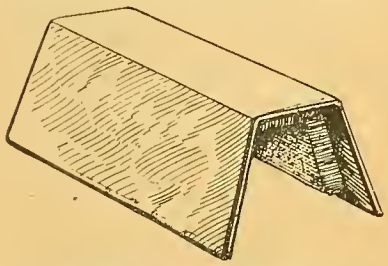
locking key is pushed inwards when the key comes out of engagement with the keyway machined on the inside of the loose flange. The loose flange can now be rotated to the right or left when the screw thread on which it revolves causes it to expand or contract the groove in which the belt runs. The locking key, of course, slides in a keyway cut on the boss of the fixed flange. As this has ample bearing surface, it should hold the loose flange quite firmly and prevent rocking. (J. Dalman and Sons, Birmingham.)

The East London Rubber Co. are making a special point during the coming season of their "Bar-Latch" motor cycle stand, a stand which, owing to its sound design and the ingenuity it displays, calls for the closest attention. The casting forms a clip and a bracket attached to the chain stays. On this casting is mounted a hinged leg set at an angle; this leg engages alternately with two spring catches, also mounted on the same casting. On the catch being released the leg moves from the horizontal position to the downward position, and automatically engages with a catch on the lower of the two bars; the machine is then

One of the East London Rubber Co.'s handy accessories, the Kerry Bar-Latch Motor Cycle Stand. When out of action, the legs are swung back to a horizontal position.

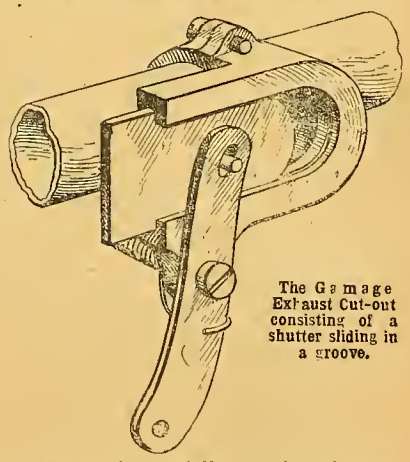
pulled towards the rider and the opposite leg treated in the same manner. The stand is extremely simple and very quickly put into action. To disengage the catch it is merely necessary to press the corner with the finger. The price of this stand has been considerably reduced. (The East London Rubber Co., 29-31, Great Eastern Street, E.C.)

Since the motor cycle first came into existence the firm of A. W. Gamage, Ltd., have never ceased to carry a large stock of accessories specially suited to readers of this paper, and with the increased popularity of the pastime, they have increased this stock to such an extent that the motor cyclist is nowhere better looked after than at this famous Holborn House. Leather belts especially require careful attention when the roads are muddy, as the particles of flint get driven into the leather and turn the belt into a grinding machine, which rapidly destroys the best of steel pulleys. In days gone by motor cyclists had to remove the flint with



Warren's Belt Cleaner, sold by A. W. Gamage, Ltd The interior is lined with file card.

an old pocket knife—a long, tedious, and dirty process. With the aid of a special belt cleaner now placed on the market by A. W. Gamage, Ltd., which consists of a steel wire brush, shaped to fit round the belt, this wearisome and uncleanly operation may be quickly and comfortably accomplished. The Gamage exhaust cut-out, which clips round the exhaust pipe, and consists of a shutter sliding in



The Gamage Exhaust Cut-out consisting of a shutter sliding in a groove.

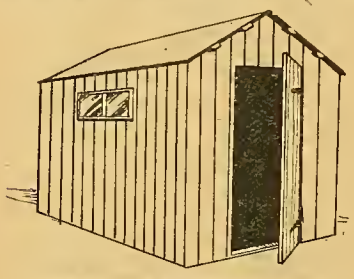
a groove, is specially worthy of attention, as it is well-designed and likely to prove gastight. The Gamage exhaust whistle and a small brass mascot, which may appeal to the more superstitious motor cyclists, and a set of folding pocket spanners, are a few of the many attractive motor cycle accessories which we recently inspected. (A. W. Gamage, Ltd., Holborn, E.C.)

The Hanover Rubber Co. sell a very excellent adjustable belt fastener with patent quickly detachable link. The Shamrock-Gloria belt has been improved in that the grooves are deepened, rendering the belt more flexible than before. The S.G. butt-ended air tubes, S.E. rubber-studded bands (which can be fitted to any make of cover), an excellent belt punch, a rubber strap with a hook at one end and an eye at the other, and a good elastic rubber handle-bar cover, complete the numerous accessories which this firm offers to the public. (The Hanover Rubber Co., 29-31, Old Street, E.C.)

Gardam and Sons, Staines, have produced for the benefit of motor cyclists and tricar owners some exceedingly

Accessories and Equipment.

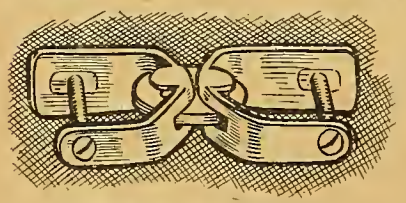
serviceable houses for the storage of their machines. These houses are strongly made of best planed, tongued, and grooved boards fitted on a strong frame, the roof being of matchboards, covered with patent Stoniflex roofing,



One of Gardam's Motor Cycle Houses.

requiring no tarring. If preferred, rebated or chamfered weather boards may be had. Prepared boards, ⅞in. thick, nailed to heavy joists, form the floor. A glazed window, the size of which varies according to the desire of the purchaser, is inserted, and the door is treated with a special wood preservative, being vermin and damp-proof, and a strong lock is provided. These houses vary in size from 6ft. to 10ft. in length, 3ft. to 8ft. in width, and 6ft. to 8ft. in height. Immediate delivery can be given, and the sections are plainly marked before leaving the works, so that re-erection is easy. Inside benches are provided, these being made to fall flat against the wall when not required, and a cupboard with lock completes the equipment of a most serviceable motor cycle house, which is reasonably priced withal. (W. Gardam and Sons, Ltd., The Wharf, Staines, Middlesex.)

In the early days of motor cycling when rubber belts were unknown, the twisted belt was going out of fashion, and the leather V belt had only just become popular, the hook fastener was still in vogue. It was a tiresome contrivance, and in those days belts were always a trouble to fasten up. With their Simplex belt fastener, Messrs. Herwin, Canny, and Co. were the first people to place on the market a really reliable invention, and to them the thanks of all motor cyclists are



The Simplex Belt Fastener.

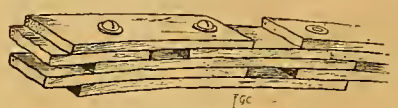
due. Of the reliability of the Simplex fastener there can be no doubt, as one of them was used by Collier when he won the 1909 Tourist Trophy Race. Instead of the screws engaging solely with the body of the fastener they now screw into special nuts and so a firm joint is made. The same firm makes also a detachable fastener and deals in general accessories. (Herwin, Canny, and Co., 36, William Street, Woolwich.)

Among the latest accessories marketed by W. W. Genn are an exhaust whistle for motor cycles which fits on the exhaust pipe, and is equally effective on engines with one or more cylinders. It is operated by foot, and is doubtless a splendid road clearer. Another item is a silencer fitted with exhaust whistle or cut-out. The silencer is cast in aluminium and is guaranteed silent. The "cut-out" cuts out half the silencer, and is made suitable for single-cylinder machines up to 4 h.p. and twin-cylinders up to 8 h.p. If desired an exhaust whistle can be fitted in addition. Mr. Genn also markets an auxiliary air inlet which fits on the inlet pipe and gives a wider range of mixture. It is also useful on a hot day when the engine sometimes requires more air than can be given by the additional air openings to the carburetter. (W. W. Genn, Gap Road, Wimbledon, S.W.)

The Druid Girder Spring Fork is very effective, and is seen on many up-to-date motor bicycles.

Sufficient proof of the efficiency of the Druid spring fork is to be found by reason of its great popularity. It is fitted to many up-to-date machines made by big firms. in addition to being in strong demand as an accessory for bringing old pattern mounts up to modern requirements. It is neat in appearance, and, moreover, permits of the use of a front rim brake. (A. Drew, Conybere Street, Birmingham.)

The Lomax belt is built up of five overlapping sections of chrome leather, fastened together with copper rivets, as shown. Washers are placed under the screws on the top ply to prevent the

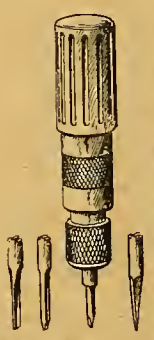


The "Lomax" Built-up Belt.

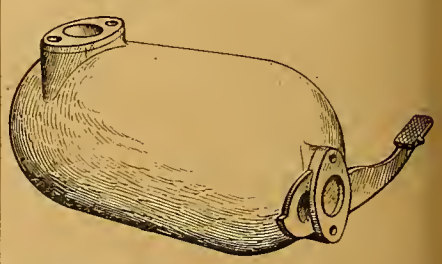
heads pulling through under the strain of transmission. In place of the usual belt fastener, screws are fitted to a few of the joints instead of rivets. All that is required is to remove one of the screws when the belt can be adjusted to an inch. (The Lomax Tyre Co., Birmingham.)

The "Clair" silencer, sold by J. C. Lyell and Co., consists of a series of metal cups which fit one into the other, leaving a space between each at the bottom. The holes in these cups are set in diametrically opposite positions, or if it is desired to give a freer passage to the exhaust gases they may be set in line. Another ingenious device for which the same firm are responsible is the concentric Pilot valve, which really consists of two valves, one inside the other. It is not always realised that the exhaust valve has to open against great pressure, and in the case of the concentric Pilot valve (see illustration on the next page), the area of the small internal valve offers a smaller resistance to the pressure of the gases, and also serves to conduct away part of the charge before the large valve opens. The makers' statement is that the ordinary valve has to be opened against a total pressure varying from 40 lbs. to 120 lbs. according to the area of its head. For example, a valve with an area equalling one square inch, opening against a pressure of 40 lbs., at the rate of ten times per second (1,200 r.p.m.), has to overcome a resistance equivalent to 24,000 lbs. per minute. It will, therefore, be seen that this is the cause of a very seen that this is the cause of great loss of power. (J. C. Lyell and Co., 55, Victoria Street, S.W.)

One of the most recent accessories to be seen at Hunt's Stores is a particularly neat silencer in aluminium with a brass foot-operated cut-out. This silencer is claimed to be most efficient in deadening the sound of the exhaust, as the exit holes are many and small, and are largely distributed over the exterior surface. Hunt's Stores have also just introduced a small, neat, and inexpensive air inlet for fitting to the inlet pipe, which should be a boon to those who study economy in petrol consumption. It consists merely of a cap with a milled head fitting over a short tube connected with the inlet pipe. In each are holes placed at intervals, and when these coincide air is admitted to the mixture. The control is effected by rotating the milled head of the cap. Two other noteworthy specialities are a deep note horn known as the Serpentine, a patent leather magneto cover, and a new all-metal tool pad. The latter accessory is particularly interesting, as it is both well made and ingenious; the



Hunt's Tool Pad.

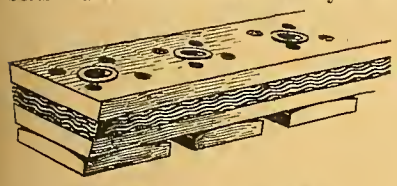


A Cast Aluminium Silencer with foot-operated cut-out. Sold by Hunt's Stores.

chuck form tool holder is attached to the receptacle which serves as a handle, while the tools contained are of a useful nature. (Hunt's Stores, Newgate Street, E.C.)

Accessories and Equipment.

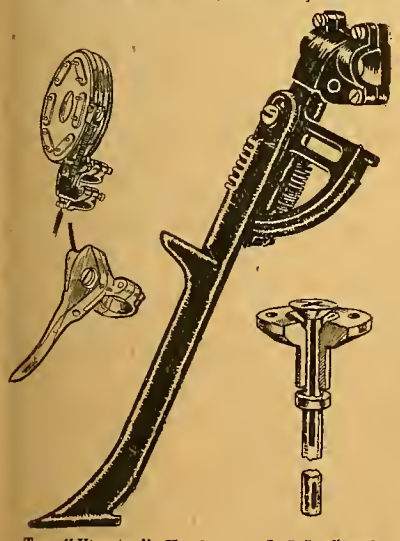
Pollin belts are built up with two or more layers of rawhide with ordinary leather V pieces riveted on the underneath at intervals. Some of these belts have an intermediate layer of



Pollin's Rawhide and Canvas Belt.

canvas to prevent stretching. They are soundly constructed articles, and from experience we have had with them, know that they give satisfaction. (W. Pollin, Spalding, Lincs.)

The Ukantes stands are made in several models which work on practically the same principle. Part of the casting forming the bracket which is attached to the chain stays takes the form of a quadrant, the extremities of which are slotted, and at the upper end of the leg is a slot, through which a pin passes. The leg is provided with a spring which keeps it normally up against the pin so that a boss on the leg is in engagement with one of the slots on the quadrant. There is a further boss on the outside of the leg enabling the latter to be disengaged from the slot by means of the pressure of the rider's foot. The Ukantes quickly applied prop works on this method, and when in action projects outwards, and allows the machine to be propped up when the rider wants to make a brief halt. When out of action the prop is parallel with the chain stays. The Ukantes popular stand works on a similar method to the above. To put the stand into action, it is only necessary to pull out one of the legs, lean the machine a few inches away, pull down the leg until it engages in the correct slot, then pull the machine forward, and do the same with the other leg. The Ukantes La Grande stand is the same except that the leg is provided with a trigger-locking device. The Ukantes sidecar jack works similarly, but, of course, only one is used to jack the wheel off the ground. This stand may be put into operation by the foot. It is also made in two sizes for heavy and lightweight motor bicycles. Price and Co. also make a speciality of front wheel stands, the advantages of which are appreciated by all who have suffered front wheel punctures. A brake which is very quickly and easily dismounted, and thus allows the back wheel to be removed without difficulty is the Ukantes duplex and triplex band brake for rear and front wheels. It consists of a coil with a hook at either end loosely encircling the belt drum, of which one hook is attached to the bracket fastening to the chain stay and the other to a link fastened to the end of the Bowden control wire. (Price and Co., 25, Rosebery Avenue, London, E.C.)



The "Ukaotes" Hand-controlled Band Brake and quickly-applied Prop.

J. C. Lyell and Co.'s Concentric "Pilot" Valve (see previous page).

"Ideal" Sprlog Fork.
